## NASA STI Program . . . in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA scientific and technical information (STI) program plays a key part in helping NASA maintain this important role.

The NASA STI program operates under the auspices of the Agency Chief Information Officer. It collects, organizes, provides for archiving, and disseminates NASA's STI. The NASA STI program provides access to the NASA Aeronautics and Space Database and its public interface, the NASA Technical Report Server, thus providing one of the largest collections of aeronautical and space science STI in the world. Results are published in both non-NASA channels and by NASA in the NASA STI Report Series, which includes the following report types:

- TECHNICAL PUBLICATION. Reports of completed research or a major significant phase of research that present the results of NASA programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA counterpart of peerreviewed formal professional papers, but having less stringent limitations on manuscript length and extent of graphic presentations.
- TECHNICAL MEMORANDUM. Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.
- CONTRACTOR REPORT. Scientific and technical findings by NASA-sponsored contractors and grantees.
- CONFERENCE PUBLICATION. Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or co-sponsored by NASA.
- SPECIAL PUBLICATION. Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.
- TECHNICAL TRANSLATION. Englishlanguage translations of foreign scientific and technical material pertinent to NASA's mission.

Specialized services also include creating custom thesauri, building customized databases, and organizing and publishing research results.

For more information about the NASA STI program, see the following:

- Access the NASA STI program home page at http://www.sti.nasa.gov
- E-mail your question via the Internet to help@sti.nasa.gov
- Fax your question to the NASA STI Help Desk at 443-757-5803
- Phone the NASA STI Help Desk at 443-757-5802

#### Abstract

The Airborne Precision Spacing (APS) team at the NASA Langley Research Center (LaRC) has been developing a concept of operations to extend the current APS concept to support dependent approaches to parallel or converging runways along with the required pilot and controller procedures and pilot interfaces. A staggered operations capability for the Airborne Spacing for Terminal Arrival Routes (ASTAR) tool was developed and designated as ASTAR10. ASTAR10 has reached a sufficient level of maturity to be validated and tested through a fast-time simulation. The purpose of the experiment was to identify and resolve any remaining issues in the ASTAR10 algorithm, as well as put the concept of operations through a practical test.

The experiment was designed to progress through three comparisons, building up a validation of ASTAR10 and then testing ASTAR10 for performance. First ASTAR9 and ASTAR10 were given identical one-runway scenarios, and the results were compared for consistency. Second, ASTAR10 was given a two-target scenario and a one-runway scenario designed to produce the same spacing. ASTAR10's performance was then tested under various criteria, including wind forecast error, different runway separations, and both one-target-two-runway and two-target-two-runway scenarios.

The work resulted in significant insights to be integrated into the NASA Langley Air Traffic Operations Lab (ATOL) and Cockpit Motion Facility (CMF) simulators for use in future APS studies and will aid in the preparations for subsequent human-in-the-loop (HITL) studies. ASTAR10 was validated and the significance of a secondary target was established. Both the APS Dependent Arrivals concept of operations and the ASTAR10 algorithm were refined.

## 1. Introduction

## a. Introduction

Improved arrival efficiency, in terms of both capacity and environmental impact, is an important part of improving National Airspace System (NAS) operations. The Airborne Precision Spacing (APS) team at the NASA Langley Research Center (LaRC) has been developing a concept of operations to extend the current APS concept to support dependent arrivals to parallel approaches along with new pilot and controller procedures and pilot interfaces [1]. This is intended to allow aircraft managing their own spacing to land on parallel runways, achieving improved arrival precision and airport capacity while also allowing aircraft to utilize Optimized Profile Descents (OPD) to improve fuel efficiency. This would result in greater aircraft throughput at the runways, less fuel consumption and noise on approaches, and Air Traffic Control (ATC) traffic planning at a more strategic level [2-4]. This system could be utilized at existing airports as well as considered in the design of future airports.

To achieve successful development and field-testing of integrated air/ground arrival operations procedures, the technology readiness level, or maturity, of the airborne spacing tool needed to be increased. Tools, procedures, and interfaces to allow airborne spacing based on two targets were developed to expand current airborne spacing operations to support dependent, parallel approach operations (also called staggered operations). A staggered operations capability for the Airborne Spacing for Terminal Arrival Routes (ASTAR) tool was developed and designated as ASTAR10. The tool allows
spacing relative to two target aircraft including one that lands on a different runway. The ASTARequipped aircraft is instructed to achieve the assigned spacing behind two aircraft, one landing on the same runway, resulting in in-trail spacing, and the other landing on a parallel runway, resulting in stagger spacing. The required stagger distance is dependent on the distance between runway centerlines. A runway separation of 2500 ft to 4000 ft requires a 1.5 nmi stagger distance, while a separation 4000 ft to 9000 requires a 2.0 nmi stagger distance.

ASTAR10 has reached a sufficient level of maturity to be validated and tested. A simulation experiment of the new precision spacing concept was performed to allow for refinements to the concept of operations as well as provide a first look at possible benefits and system performance improvements of these new operations. The work resulted in significant insights to be integrated into the NASA Langley Air Traffic Operations Lab (ATOL) and Cockpit Motion Facility (CMF) simulators for use in future APS/ASDO studies and will aid in the preparation for subsequent human-in-the-loop (HITL) studies. This experiment consisted of analyses of fundamental performance and operations. It did not include any HITL elements or advanced performance elements.

## b. Operations Terminology

In this paper, four criteria are used to distinguish the particular operations. These criteria are: the number of runways in use, whether the spacing aircraft is tracking one target or two, whether the target aircraft is approaching the same runway or a parallel runway as the spacing aircraft, and whether the target aircraft's spacing criteria are the dominant criteria.

The number of runways represents a high-level variable. One-runway operations mean that only one runway is in use, thus all aircraft land on that runway, in-trail behind one another, with only one possible target. If more than one parallel runway is in use, the operation is a parallel approach operation. This is illustrated below in Figure 1.

## Parallel runway Operations

Figure 1: One-Runway operations vs. Parallel-Runway operations.
In parallel operations, aircraft can space off of an aircraft approaching the same runway, an aircraft approaching a parallel runway, or both aircraft simultaneously. If the spacing aircraft is only spacing off of one aircraft, it is called a one-target operation. If the spacing aircraft is spacing off of aircraft approaching both runways, it is called a two-target operation. Note that in one-target operations, the spacing aircraft may space off of only the aircraft approaching a parallel runway, while ignoring an aircraft approaching the same runway, or vice versa. Also note that the number of targets only refers to how many aircraft are being used for spacing operations, not how many aircraft are present. Thus, onetarget operations may be in use when there are multiple aircraft that could be targeted. This is illustrated below in Figure 2.

Figure 2: One-Target vs. Two-Target operations.
If a target aircraft is approaching the same runway as the spacing aircraft, the spacing is said to be in-trail spacing. If the target aircraft is approaching a parallel runway, the spacing is said to be stagger spacing. Two-target operations necessarily use both in-trail and stagger spacing, while one-target operations may use either one. This is illustrated above in the one-target diagrams of Figure 2.

Finally, in two-target operations, a distinction is made between a primary target and a secondary target. When determining this, the spacing aircraft calculates a resultant spacing position for each spacing aircraft. The aircraft whose spacing interval results in a spacing position further back is defined as the primary target, while the secondary target's spacing interval results in a closer spacing position. The spacing aircraft precisely meets the spacing interval of the primary aircraft, while exceeding or meeting the spacing interval of the secondary aircraft. This is illustrated below in Figure 4.

Figure 3: Primary vs. Secondary targets.

## 2. Objectives

The purpose of the experiment was primarily to identify and resolve any remaining issues in the ASTAR10 algorithm, as well as put the concept of operations through a practical test. This was done during the development of the experiment scenarios. The experiment itself was divided into two segments. The first segment was used to validate ASTAR10 against ASTAR9, the previous iteration of the algorithm, while the second segment was used to address several research questions.

## a. Research Questions

During the development of the concept of operations several research questions were identified which could be answered by one or more system performance studies. This experiment was designed to address two of these:

- What is the impact of two-target operations versus one-target operations in a parallel approach environment?
- Hypothesis: Two-target operations will yield fewer separation violations against the secondary aircraft, since spacing is being managed against both targets.
- How stable are one- and two-target stagger operations?
- Hypothesis: Both operations will be equally stable.

## 3. Methodology

## a. Airspace Environment

Portions of the Dallas-Ft. Worth International Airport (KDFW) airspace environment were simulated in the experiment. To meet the objectives of this experiment, two pairs of runways were needed: one pair separated by 2500 ft to 4300 ft and the other pair separated by 4300 ft to 9000 ft . No two pairs of KDFW runways satisfied these criteria so a new "virtual" runway was added. Runway 18 V was placed between existing runways 18 R and 17 R . Approaches to runways 18 R and 18 V are separated by 2500 ft while runways 18 V and 17 R are separated by 5100 ft . OPDs were designed that ended at the appropriate ILS for each runway. A chart of the $18 \mathrm{R} / 18 \mathrm{~V} / 17 \mathrm{R}$ arrival paths is shown in Figure 5. The southwest arrival path is split into two separate routes farther out (at approximately 153 nmi out from the runway). Note that the final approach leg for approaches from the west was extended to avoid head-on base legs and introduce the possibility of an aircraft intercepting its final approach leg prior to that its stagger target aircraft doing so.

Figure 4: Approach chart for KDFW.

## b. Traffic Scenario

The traffic scenarios for this batch study consisted of 50 aircraft to each of the selected parallel runways (e.g., KDFW 18 R and 18 V or 18 V and 17 R ). Initialization of the aircraft was at cruise altitudes and speeds approximately 60 nmi prior to Top-of-Descent. Aircraft spacing within or between streams consisted of a mix of in-trail and staggered aircraft depending on the scenario objectives. Several sets of initial parameters (aircraft type, weight, altitude, and speed; route distribution) were used across test conditions to enable aircraft-to-aircraft performance comparisons between the test conditions, while also providing multiple variations.

## c. Aircraft Distribution

The aircraft type and route distributions were generated from statistics derived from a single day of operations at DFW. The aircraft types observed were then pruned to aircraft types available for simulation in TMX. The results are shown in Table 1 below.

Table 1: Aircraft Distribution

| BADA <br> Model* | Aircraft Types | Ref. Mass Mkg | Ref. <br> Weight Klb | $\begin{gathered} \mathrm{V}_{\text {stall }} \\ \text { Landing } \\ \hline \end{gathered}$ | Number Observed | Observed | Percent Used |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| CRJ1 | Canadair Regional Jet | 21.0 | 46.2 | 108 | 76 | 7.8 | 10 |
| A319 | A319 | 60.0 | 132.0 | 94 | 66 | 6.8 | 10 |
| B737 | B737-700 | 60.0 | 132.0 | 103 | 87 | 8.9 | 15 |
| MD83 | MD-83 | 61.2 | 134.6 | 112 | 633 | 64.9 | 25 |
| B753 | B757 | 101.6 | 223.5 | 109 | 71 | 7.3 | 15 |
| B763 | B767-300 | 150.0 | 330.0 | 113 | 16 | 1.6 | 10 |
| B773 | B777 | 237.6 | 522.7 | 111 | 24 | 2.5 | 10 |
| B744 | B747-700 | 285.7 | 628.5 | 118 | 2 | 0.2 | 5 |

*The BADA Model number represents the identification of the aircraft model in the simulation software
The observed statistics significantly over-represented MD83 aircraft and the northeast quadrant. As the purpose of the experiment was not to model an actual DFW traffic environment, these statistics were modified to represent a more general distribution. The aircraft type distribution can be seen above in the Percent Used column, while the quadrant distribution was split $50 / 50$ by east/west and $60 / 40$ by north/south, resulting in an aircraft distribution of $30 / 30 / 20 / 10 / 10$ for the northeast, northwest, southeast, and two southwest routes.

## d. Wind

One of the wind conditions described in Ref [5] was used in this experiment. The wind scenario chosen was the data set for March 6, 2009. It was selected as having reasonable characteristics in strength, direction, and variation.

Charts of the selected data set were inspected to determine ten altitudes that would produce representative interpolations of the four tabulated parameters, true wind speed and direction, and forecast wind speed and direction. The truth wind was used to determine actual aircraft performance, while the forecast wind was used for scheduling and aircraft trajectory predictions. Ten data points were used to describe the truth and forecast winds in the TMX software. The results of this process are depicted in Figure 6.

Figure 5: Truth and Forecast wind from the 06MAR09 dataset with altitudes selected for this experiment.
The characteristics shown in the chart are wind speeds of 60-70 kt at cruise altitudes, $30-40 \mathrm{kt}$ between 20,000 and $10,000 \mathrm{ft}, 40-50 \mathrm{kt}$ between 10,000 and 5000 ft , and 15 kt at the airport surface. The wind direction is WNW at cruise altitudes, S between 20,000 and $13,000 \mathrm{ft}$, SW between 13,000 and 8000 ft , and SSE at the surface. Aircraft on approach encountered slight crosswinds from the right veering to 20 degrees from the left at the runway threshold.

The wind models for this study were then generated using the interpolated speed and direction values for the ten selected altitudes. The wind fields were laterally homogeneous throughout the region of the simulation.

## e. Independent Variables

The independent variables for this experiment were wind (varying from no wind, to wind with accurate forecast, to wind with a forecast error), runway separation ( 2500 ft or 5100 ft ), and number of target aircraft (one- or two-target operations). The final experiment matrix is provided below in Table 2:

Table 2: Final Experimental Matrix

| Scenario | Active Runways | Wind/Forecast Error | Spacing/Operations |
| :---: | :---: | :---: | :---: |
| 1 | 18R | None/No | In-Trail One-Target |
| 2 | 18R | None/No | In-Trail One-Target modified spacing goal (see text) |
| 4 | 18R/18V | None/No | Two-Target |
| 5 | 18V/17R | None/No | Two-Target |
| 6 | 18R/18V | Nominal/No | Two-Target |
| 7 | 18V/17R | Nominal/No | Two-Target |
| 8 | 18R/18V | Nominal/Yes | Two-Target |
| 9 | 18V/17R | Nominal/Yes | Two-Target |
| 10 | 18R/18V | None/No | One-Target |
| 11 | 18V/17R | None/No | One-Target |
| 12 | 18R/18V | Nominal/No | One-Target |
| 13 | 18V/17R | Nominal/No | One-Target |
| 14 | 18R/18V | Nominal/Yes | One-Target |
| 15 | 18V/17R | Nominal/Yes | One-Target |

Scenario 1 was run with both ASTAR9 and ASTAR10 software, thereby providing a validation test for ASTAR10's one-runway operations. Scenarios 2 and 4 were designed to produce the same spacing between sequential aircraft, but with one-runway operations for scenario 2 and two-runway, two-target operations for scenario 4 , thereby providing a validation test for ASTAR10's two-target operations. From there on, scenarios 4 through 9 and scenarios 10 through 15 were designed as mirror sets, with scenarios 4 through 9 using two-target operations while scenarios 10 through 15 used one-target operations. Within each operations grouping of scenarios, the scenarios were also divided between wind conditions. Thus, scenarios $4,5,10$, and 11 experienced no wind, scenarios $6,7,12$, and 13 experienced wind with an
accurate forecast, and scenarios $8,9,14$, and 15 experienced wind with a forecast error. Scenarios also alternated between runway configurations, so that all even-numbered scenarios landed on runways 18 R and 18 V , while all odd-numbered scenarios landed on runways 18 V and 17 R . For the purposes of comparing operations differences, this allows a direct 1 -to- 1 comparison of scenarios 4 and 10,5 and 11, 6 and 12,7 and 13,8 and 14 , and 9 and 15 , while also isolating wind conditions and runway differences. The statistical analyses compared the scenarios accordingly.

## f. Dependent Variables

The dependent variables tracked for data analysis, taken from the simulation software, were the closest direct-line distance between the spacing aircraft and the traffic-to-follow (TTF2ClosestCG), the arrival error (CrossingTimeError), the total number of speed changes (SpdChanges(total)), and the actual time of arrival (ATA). The closest distance was used to identify separation violations with respect to the second target when comparing scenarios 4 through 9 to scenarios 10 through 15. If the closest point was below the minimum separation requirements, a violation would have occurred. Arrival error was used as a performance metric when comparing scenarios 4 through 9 to scenarios 10 through 15. The ideal arrival error was zero, with either a positive or a negative error indicating less than perfect performance. The speed changes generated by the ASTAR10 algorithm to meet the spacing goal were not separated from the speed changes required by the arrival procedure. Arrival time was used to calculate achieved stagger spacing in Scenario 4 and achieved in-trail spacing in Scenario 2. To do this, the arrival time of one aircraft was compared to that of the following aircraft. The difference between them was the in-trail spacing for scenario 2 and the stagger spacing for scenario 4 . The scenarios were designed so that Scenario 4's stagger spacing should have been comparable to Scenario 2's in-trail spacing. Arrival error could not be used because of the nature of the spacings being compared. Arrival time was used solely for validation purposes. Closest distance was used to answer the first research question. Arrival error and the number of speed changes were used to answer the second research question.

## g. Spacing Commands

Spacing commands were given to the aircraft depending on their in-trail or stagger requirements. The required in-trail wake-vortex separations were $2.5 \mathrm{nmi}, 4 \mathrm{nmi}$, and 5 nmi , depending on the interaction of leading and following aircraft weight class. These requirements were given a 0.5 nmi buffer and then converted into times using an assumed final approach speed (FAS) of 139 knots and incorporating the forecast wind. The stagger spacing requirements were 1.5 nmi for $18 \mathrm{R} / 18 \mathrm{~V}$ and 2.0 nmi for $18 \mathrm{~V} / 17 \mathrm{R}$. These requirements were given a 0.2 nmi buffer, and the $18 \mathrm{R} / 18 \mathrm{~V}$ requirement was expanded to 2.1 nmi to ensure 3 mile separation prior to final approach (required to maintain radar separation prior to final approach, see section 7.a). The stagger requirements were given as distances.

## h. Aircraft Assignments

Two sequences of 100 random numbers were generated and assigned to a sequential numbering scheme (in its original, random order) using Microsoft Excel Spreadsheet's Rand() command. The results were then separately re-ordered according to the sequences of random numbers, resulting in two random sequences of a sequential numbering scheme. Aircraft and routes were sequentially assigned to the separate sequences of random numbers according to their statistical distribution $(20 \%=20 \mathrm{AC})$. The
tables were then re-sorted according to the sequential numbering scheme, resulting in a single numbering scheme ordering from 1 to 100 and a random association of aircraft and routes.

Aircraft were taken from the random table and assigned to runways in order, according to direction of origin (routes from the east were assigned to the eastern runway, etc). This resulted in two sequences of random aircraft, one to each runway. The runway assignments were then blended together in a stagger pattern, with aircraft being assigned to alternating runways, and in-trail spacing time was derived from the resulting table. Each aircraft then had a separate Estimated Time of Arrival (ETA) calculated from its intrail spacing and stagger spacing time separations. The larger of the two values becomes the primary spacing command. The aircraft this command related to was called the primary aircraft, while the other aircraft being spaced against was called the secondary aircraft. In this simulation, secondary aircraft were assigned a 'no closer than' spacing command, meaning that positive errors (representing being farther away than the spacing command required) were ignored. The ETA for next aircraft was then calculated based on those for previous aircraft and specified spacing times. The time-differences between the aircraft were then calculated. This sequence of aircraft, routes, and ETA differences was then entered into the existing Scenario Generator to generate a TMX input file with ASTAR9 (in-trail only) spacing commands. This file was then manually edited to include the appropriate ASTAR10 stagger and secondary-target spacing commands. Below, Figure 7 details an example random schedule generation of four aircraft, while Figure 8 shows how the scheduled spacing and primary/secondary relationships were determined.

## As an example:

| 0.0357 | 1.2583 |
| :--- | :--- |
| 1.2576 | 0.2485 |
| 0.5137 | 4.2153 |
| 8.2145 | 2.9543 |

One could take the random numbers

| 0.0357 | 1 | 1.2583 | 1 |
| :--- | :--- | :--- | :--- |
| 1.2576 | 2 | 0.2485 | 2 |
| 0.5137 | 3 | 4.2153 | 3 |
| 8.2145 | 4 | 2.9543 | 4 |

Assign a sequential order of 1-4 to each

| 0.0357 | 1 | 0.2485 | 2 |
| :--- | :--- | :--- | :--- |
| 0.5137 | 3 | 1.2583 | 1 |
| 1.2576 | 2 | 2.9543 | 4 |
| 8.2145 | 4 | 4.2153 | 3 |

| 0.0357 | 1 | MD83 | 0.2485 | 2 | AEX |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 0.5137 | 3 | B757 | 1.2583 | 1 | BGD |
| 1.2576 | 2 | B757 | 2.9543 | 4 | BGD |
| 8.2145 | 4 | A319 | 4.2153 | 3 | FSM |

| 0.0357 | 1 | MD83 | 1.2583 | 1 | BGD |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 1.2576 | 2 | B757 | 0.2485 | 2 | AEX |
| 0.5137 | 3 | B757 | 4.2153 | 3 | FSM |
| 8.2145 | 4 | A319 | 2.9543 | 4 | BGD |

| MD83 | BGD |
| :--- | :--- |
| B757 | AEX |
| B757 | FSM |
| A319 | BGD |

Assign aircraft types to the corresponding routes

| B757 | BGD | B757 | AEX |
| :--- | :--- | :--- | :--- |
| A319 | BGD | MD83 | FSM |

Separate them according to their approaches. Since AEX and FSM approach from the same direction, while BGD approaches from the other direction, the results should look like

| B757 | BGD |
| :--- | :--- |
| B757 | AEX |
| A319 | BGD |
| MD83 | FSM |

Finally, order them in a staggered pattern

Figure 6: Aircraft type and runway assignment example.

Figure 7: Aircraft scheduling example.

## i. Simulation Facility

Traffic Manager (TMX) software, the simulation environment for the experiment, is a multiple aircraft simulation environment developed by the National Aerospace Laboratory (NLR) of the Netherlands. It was originally designed in 1996 to study airborne separation assurance with multiple aircraft interactions in a Free Flight environment. It has been continually developed since that time by both the NLR and NASA Langley for use in a wide range or simulation projects [6]. It is capable of generating, simulating, and managing multiple aircraft simultaneously in an airspace simulation. The ASTAR development team has integrated the ASTAR10 algorithm into TMX, allowing the aircraft to fly using ASTAR10 procedures. The version of TMX used was v9.3.07. It was implemented on a single desktop computer.

## j. Runs

Each scenario was run under two different randomly generated traffic conditions, as described previously. Each of these conditions was then run twice, employing performance randomization factors built into TMX, including pilot model reaction times, atmospheric and sensor noise, and randomized sampling time. This provided a total of 4 iterations of each scenario.

## 4. Validation

## a. Purpose

The ASTAR10 algorithm represents a new modeling software package, with substantial changes from the previous iteration. It is thus important to validate its performance against the previous algorithm to ensure it maintains sufficiently accurate performance.

## b. Findings

In comparing the performance of ASTAR10 to ASTAR9, the differences between arrival spacing was compared, using ATAs. ASTAR9 presented a sample size of 198 values ( 99 for each of two traffic scenarios), while ASTAR10 presented 396 ( 99 for each of two traffic scenarios; each scenario run twice). Because of this discrepancy, the ASTAR10 data was averaged between the runs of each traffic scenario, resulting in 198 values. It was expected that there would be no difference in the spacing performance between ASTAR9 and ASTAR10. An F-test was performed to test this hypothesis. The F-value was 0.10 and the p-value was 0.75 . From this, the null hypothesis that there is no statistically significant difference between the two data sets was supported.

In comparing the performance of ASTAR10's one-target operations (scenario 2) to its two-target operations (scenario 4), a sample size of 396 values for each scenario was obtained. The F-value was 0.04 and the p -value was 0.83 . From this, the null hypothesis that there is no statistically significant difference between the two data sets was supported. The results are shown below in Figure 9.

Figure 8: Distributions of differences in ATA.

## 5. The Impact of Two-Target Operations

## a. Purpose

The first research question asked what the impact of two-target operations vs. one-target operations is. This question was asked in order to assess the importance of a secondary target. It had been considered that the aircraft may be able to maintain separation with both targets simply by monitoring their primary target aircraft, and that any secondary aircraft would necessarily stay a greater distance away. This was uncertain in ASTAR10, however, because the algorithm does not maintain current spacing, but rather predicted spacing at the runway. It is thus possible for current spacing to be either greater than or less than the desired spacing at the runway. The amount of difference between current spacing and final spacing is monitored, allowable error is reduced as an aircraft gets closer to the runway, and a spacing buffer is included to ensure that minimum separation standards are not violated. However, a secondary aircraft's error with its own primary could place it out of position, and thus too close to another trailing aircraft.

## b. Findings

In addressing the first research question TTF2ClosestCG values were compared to the required separation criteria. Each scenario had a sample size of 100 . No statistically significant variation was observed; however, a noticeable, if minor, difference was observed. While the two-target operations saw no separation violation against the secondary aircraft, the one-target operations saw a total of 4 such violations, out of a total of 2328 aircraft. Given the nature of these events, this difference is considered significant, if infrequent. Operationally speaking, one separation violation per 582 aircraft is unacceptable. These violations are occurring specifically because the spacing between an aircraft and its secondary target is not being monitored. Since the purpose of identifying a second target is to avoid separation violations with it, the hypothesis that two-target operations will see fewer separation violations against the secondary aircraft was supported. The results are below in Table 3.

Table 3: Separation Violations

| Separation <br> Violations | $1-1$ | $2-1$ | $1-2$ | $2-2$ |
| :---: | :---: | :---: | :---: | :---: |
| Scenario 4 | 0 | 0 | 0 | 0 |
| Scenario 5 | 0 | 0 | 0 | 0 |
| Scenario 6 | 0 | 0 | 0 | 0 |
| Scenario 7 | 0 | 0 | 0 | 0 |
| Scenario 8 | 0 | 0 | 0 | 0 |
| Scenario 9 | 0 | 0 | 0 | 0 |
| Scenario 10 | 0 | 0 | 0 | 0 |
| Scenario 11 | 0 | 0 | 0 | 0 |
| Scenario 12 | 0 | 0 | 0 | 0 |

| Scenario 14 | 0 | 0 | 0 | 0 |
| Scenario 15 | 0 | 1 | 0 | 1 |

## 6. Stability of Operations

## a. Purpose

The second research question asked how stable one- and two-target operations are. Because two-target operations represent a new capability, it was important to establish the stability of the aircraft arrival streams. This fact was emphasized early in the experiment development as many arrival streams resulted in periodic excessive spacing. The problem was identified as resulting from a transition from time-based stagger spacing to distance-based stagger spacing for final approach. The time-based spacing commands had been based on an average final landing speed, which was used to convert from the distance requirements to the time-based spacing command. The distance-based commands for final approach, however, allowed the ASTAR algorithm to use each aircraft's individual speed in performing calculations, thus resulting in a different spacing. Specifically, aircraft typically attempted to gain about 2 seconds. Each individual aircraft was able to do this for its own spacing, but all aircraft after them would then have to advance the same amount. Because of this, each aircraft would not only need to gain its own 2 seconds, but also 2 more seconds for each aircraft ahead of it in the arrival stream. This sum continued to build until one aircraft was incapable of making up the time, resulting in a single, large spacing error and then restarting the process. This issue was resolved by changing the stagger spacing commands to distance-based spacing throughout the entire route.

## b. Findings

In addressing the second research question, two variables were considered. Each scenario produced a total of 100 samplings in the first variable, which was the number of recorded speed changes. The results of the chi-square tests showed a statistically significant difference between scenarios 5 and 11, 6 and 12, and 7 and 13. The differences, however, were varied, showing preference for different conditions in different scenarios. The results are below in Table 4:

Table 4: Number of commanded speed changes.

| Speed Changes | 1-target | 2-target |
| :---: | :---: | :---: |
| 4 vs. 10 | 2981 | 2840 |
| 5 vs. 11 | 3181 | 3348 |
| 6 vs. 12 | 5113 | 4697 |
| 7 vs. 13 | 3408 | 4534 |
| 8 vs. 14 | 5841 | 5888 |
| 9 vs. 15 | 5104 | 4978 |

Each scenario produced a total of 100 samplings in the second variable, which was the arrival error. The results of the single-factor ANOVA, as performed for each set of scenarios, showed no statistically significant difference. Additionally, an F-Test was performed for each set of scenarios, which indicated a minor but statistically significant difference under ideal conditions as well as under wind error conditions. The results of both tests are below in Table 5 and Figure 10:

Table 5: CrossingTimeError ANOVA \& F-Test

| Scenarios | ANOVA <br> F-Value | ANOVA <br> P-Value | F-Test <br> F-Value | F-Test <br> P-Value |
| :--- | :---: | :---: | :---: | :---: |
| 4 vs. 10 | 0.122243 | 0.726707 | 0.871045 | 0.084183 |
| 5 vs. 11 | 0.039274 | 0.842957 | 0.787677 | 0.008671 |
| 6 vs. 12 | 0.167455 | 0.682494 | 0.926049 | 0.221617 |
| 7 vs. 13 | 2.363388 | 0.124609 | 1.053499 | 0.301475 |
| 8 vs. 14 | 0.179685 | 0.671758 | 0.818369 | 0.022805 |
| 9 vs. 15 | 0.173960 | 0.676729 | 1.368358 | 0.000893 |

Figure 9: CrossingTimeError.
The lack of difference under wind conditions without error as well as the lack of any such significance in the ANOVA indicate that this may be the result of a Type I error, or false positive, in the F-Test.

Because the differences in the number of speed changes commanded were inconsistent, the addition of a second target does not appear to change the stability of the operations at all.

## 7. Other Findings

## a. Separation Prior to Stagger Operations

During the development of this experiment, difficulties with maintaining separation during the stagger operations were found. The goal of the stagger operations was to achieve as high runway throughput as possible while each aircraft performed an OPD. However, it was found that, with the closer spaced runways that only required 1.5 nmi stagger distance, radar separation would not be maintained prior to the aircraft being established on their final approach course. The reduced separation standard for the staggered approach only applies once both aircraft are established on their final approach course. Effectively the aircraft had to have a 3 nmi stagger distance as they turned on to their final approach course, but 1.7 nmi stagger distance as they landed. This led them to speed up significantly to try and achieve the 1.7 nmi spacing that was used for stagger operations. This was operationally unacceptable and would lead to instabilities for a string of aircraft. This was not a problem for the further separated runways which require 2 nmi stagger spacing as the 2 nmi plus the separation between the runways achieved the 3 nmi radar separation requirement. The possible solutions would be to either provide vertical separation before the aircraft were established on their final approach course or adjust the stagger spacing to support the 3 nmi lateral separation. The former is how operations are generally handled in today's operations but would require one of the aircraft to fly a low, level segment and would lose much of the benefits the OPD was providing. The latter option was chosen and a stagger spacing of 2.1 nmi was used.

## b. Alterations to the Schedule

At the beginning of the experiment, it was intended to test whether or not the time of assignment of the stagger target was important. It was identified as stagger, rather than secondary, because a secondary aircraft may be an in-trail aircraft, and it was assumed that the in-trail aircraft would be relevant from the moment spacing was assigned. A stagger aircraft may not be within range for spacing operations until much later, however. Upon consideration of how this testing would be achieved, it was noted that assigning the stagger aircraft at a later time would change the arrival schedule of the affected aircraft if the stagger aircraft was also primary. This would then change the schedules of every aircraft behind the affected aircraft. This is the scheduling equivalent of pop-up traffic, and was designated an off-nominal condition. Testing of how ASTAR10 could manage pop-up traffic and schedule changes is a subject for further study.

## c. Stagger Aircraft as the Primary Aircraft

At the beginning of the experiment, it was conceived that the stagger aircraft would typically be the secondary aircraft. One question was how easy it would be to identify when the stagger aircraft was the primary aircraft, as well as how frequently that occurred. In the production of the initial scenarios, it was noted that the stagger aircraft being the primary aircraft, while not the norm, was not unusual. As the experiment plan was developed and spacing standards were adjusted, this changed to the point that the majority of aircraft were seeing a stagger aircraft as their primary aircraft. Throughout the whole process, it was noted that the identification of primary and secondary aircraft could follow simple rules. In a timebased system, the calculations are simple. If the in-trail spacing command is more than twice the stagger spacing command, it is primary. If it is less than twice the stagger command, the stagger command is
primary. In a distance-based system, this becomes more complicated; but because any individual airspace will have a finite set of spacing options, simple rules can be produced. For example, in the final scenarios, the stagger spacing commands were large enough that only the largest in-trail spacing command of 5 nmi was more than twice the stagger command. This meant that the stagger command was always primary unless the in-trail command was for 5 nmi , or a non-heavy aircraft following a heavy aircraft. Different stagger commands may change the transition point between in-trail and stagger spacing dominance, but would not lead to confusion, because any particular runway separation will have a set stagger command, and thus a set transition point.

In the process of analyzing this issue, another oddity was noticed. It is possible for both the in-trail aircraft and the stagger aircraft to produce the same ETA for the subject aircraft. This occurs due to a peculiar 4-aircraft structure depicted below in Figure 11:

Figure 10: Even spacing configuration.
In the depicted configuration, the first heavy acts as a fixed ETA from which everything else can be judged. The second heavy and the first large have separate and unique ETAs for their primaries and secondaries, but the second large will see the same ETA for both of them. This can be logically deduced by noting that the distance from the first heavy to the second large is the same whether taken through the second heavy or the first large. A standard should be developed for which command will take precedence, and any visualization system may need to take account of this oddity, as any visual tracking of the current spacing target may result in rapid and frequent transitions from one target to another, which could prove distracting to pilots.

## d. Schedule Sensitivity

In the original experiment plan, it was intended that time-based spacing be used for both in-trail and stagger spacing requirements. This proved problematic as the current ASTAR algorithm requires a distance-based spacing for stagger aircraft on final approach. Time-based spacing uses a single assumed FAS for all aircraft, as the calculation is done at the scheduling stage. By contrast, distance-based spacing allows ASTAR to use each aircraft's own FAS in the scenario. The conversion from one to the other inevitably produced sizable errors. Individual aircraft could cope with these errors, but the effect became cumulative, with each aircraft facing not just its own error, but also the errors of all aircraft in front of it. In implementing this distance-based spacing, it was noted that the initial stagger spacing and the final approach stagger spacing required two different spacing commands. The initial command calculated a distance-to-go or in-trail-equivalent spacing, while the second command calculated direct-line spacing. This difference produced substantial errors in the initial tests, leaving aircraft with as much as 9 seconds
to make up in final approach, with the cumulative effects exceeding the capability of following aircraft to make up. When noticeable errors persisted, more in-depth analysis showed the remaining problem was schedule-based. The schedule was such that aircraft were being delivered to the airspace too slowly, so that by the time one aircraft appeared, its lead aircraft was already too far ahead to be caught up to. The problem was traced to the assumed FAS, which was still used in scheduling calculations for all spacing commands. The initially assumed FAS of 130 kt was slower than the average FAS in the simulation, so the 'average' aircraft saw an error. In attempting to find a better assumed FAS, it was noted that variations as small as 1 kt produced substantial changes in the behavior of the traffic stream across the full 100 aircraft. The final solution was a FAS of 139 kt , with wind influencing the schedule for appropriate scenarios. This still was not without error, however, as the A319s in the simulation still occasionally violated separation even with a half-mile buffer zone, resulting in a total of 33 violations out of 4752 . These were caused by A319 final approach speeds in the range of $124 \mathrm{kt}, 15 \mathrm{kt}$ slower than the assumed FAS, resulting in the same time spacing command being converted into substantially lower distance spacing ( 4.85 nmi vs. 5.5 nmi ). In future research, it is suggested that scheduling use final approach speeds based on individual aircraft types.

## 8. Conclusions

This experiment was conducted in an effort to refine and test the ASTAR10 algorithm and the underlying concept of operations. During the development of this experiment, a number of software and integration errors were detected and resolved. The issue of time-based spacing versus distance-based spacing was also highlighted for further discussion. Additionally, several questions as to the performance of the algorithm, such as how it would meet the radar separation requirement, what impact alterations to the spacing schedule would have, and how frequent and obvious the stagger aircraft being the primary aircraft would be, were addressed. Finally, ASTAR10 was validated and the use of a secondary target was shown to be important for performance, though not as important as had initially been thought.

## 14. ABSTRACT

The Airborne Precision Spacing (APS) team at the NASA Langley Research Center (LaRC) has been developing a concept of operations to extend the current APS concept to support dependent approaches to parallel or converging runways along with the required pilot and controller procedures and pilot interfaces. A staggered operations capability for the Airborne Spacing for Terminal Arrival Routes (ASTAR) tool was developed and designated as ASTAR10. ASTAR10 has reached a sufficient level of maturity to be validated and tested through a fast-time simulation. The purpose of the experiment was to identify and resolve any remaining issues in the ASTAR10 algorithm, as well as put the concept of operations through a practical test.
