#### Abstract

Main purpose of this study is to determine the accuracy of the line spring model, to investigate the effect of interaction between two and three cracks, and to provide extensive numerical results which may be useful in applications. Line spring model with Reissner's plate theory is formulated to be used for any number and configurations of cracks provided that there is symmetry. This model is used to find stress intensity factors for elliptic internal cracks, elliptic edge cracks and two opposite elliptic edge cracks. Unfortunately, because of the unavailability of previous work done on the cases considered, only stress intensity factors for central elliptic crack could be compared with other methods. Despite the simplicity of the line spring model, the results are found to be surprisingly close.

## 1. INTRODOCTION

From the viewpoint of practical applications, the analysis of a part through crack in a structural component which may locally be represented by a "plate" or a "shell" is certainly one of the most important problems in fracture mechanics. In its general form, the problem is a three-dimensional crack problem in a bounded geometry where the stress fields perturbed by the crack interacts very strongly with the surfaces of the solid. At present, even for the linearly elastic solids, a neat analytical treatment of the problem very heavily rely on some kind of numerical technique, such as alternating method, [5], [6], or boundary integral equation method, [7]; but most notably on the finite element method, [8]-[10]. The renewed interest in recent years in the so called Mine-spring model" first described in [3] has been due partly to the desire of providing simpler and less expensive solutions to the part-through crack problem and partly to the fact that for certain important crack geometries, the model seems to give results that have an acceptable degree of accuracy.

In a plate or shell containing a part-through crack and subjected to membrane and bending loads, the net ligament(s) around the crack would generally have a constraining effect on the crack surface displacements and rotations. The basic idea underlying the "line-spring model" conslsts of approximating the three-dimensional
crack problem by a two-dimensioral coupled bending-membrane problem through the reduction of the net ligament stresses to the neutral surface of the plate or shell as a membrane load $N$ and a bending moment $M$. In the resulting two-dimensional problem, the crack surface displacements are represented by a crack opening displacement $\delta$ and a crack surface rotation 0, referred to, again, the neutral surface. The quantities $N, M, 8$ and $B$ are assumed to be functions of a single variable, namely the coordimate $x_{1}$, along the crack in the neutral surface (Fig. 1). The pair of functions ( 8,8 ) or ( $N, M$ ) are determined from the corresponding mixed boundary value problem for the plate or the shell having a through crack in which $N$ and $M$ are treated as unknown crack surface loads. Once $N$ and $M$ are determined, the stress intensity factors are evaluated from the twodimensional elasticity solution of a strip under the membrane force $N$ and the bending moment $M$.

The model introduced in [3] is based on the classical theory. However, the asymptotic stress field around the crack tip given by classical plate bending theory is cot consistant with the elasticity solutions, whereas a transverse shear theory (such as that of Reissner's) which can accomodate all stress and moment resultants on the crack surface seperately (i.e., three boundary conditions in plates, five in shells) give results which are identical to the asymptotic solutions obtained from the plane strain and anti-plane shear crack problems [2], [11]. The line spring model was later used
in [12], [13] to treat the longitudinal part-through orack problem in a cylinder by using the classical shell theory and in [1], [14] by using transverse shear theory, Rather extensive results for corner cracks and for collinear surface cracks in a plate having a finite width are given in [15]. The similar problem of surface crack-boundary interaction in a cylindrical shell with a free or a fixed boundary is considered in [16] and [17].

In this study, stress intensity factors for elliptic internal cracks under pure bending and tension, and for collinear elliptic edge cracks under pure tension will be studied by using the linespring model with Reissner's plate bending theory. Interaction of two and three identical elliptic edge and internal creaks will also be studied by using the same method.

## 2. FORMOLATION OF THE PROBLEM

### 2.1 Governing Integral Equations

The problem under consideration is a surface or an internal crack problem for a relatively thin-walled structural component which is solved basically as a plate or shell problem. In the usual notation $u_{1}, u_{2}, u_{3}$ are the components of the displacement vector, $\beta_{1}$ and $\beta_{2}$ are the angles of rotation of the normal to the neutral surface in $x_{1} x_{3}$ and $x_{2} x_{3}$ planes, respectively, and $N_{i j}, M_{i j}$ and $\nabla_{i}(1, j=1,2)$ are respectively the membrane, moment and transverse shear resultants (Fig. 1).

Related mixed boundary value problem for any number of aracks häs been formulated in [15] by using Reissner's plate bending theory. The derivatives of the crack surface displacement and the crack surface rotation on the neutral surface are chosen as the unknown functions. Fredholm kernels $k_{1}(x, t)$ and $k_{2}(x, t)$ in [15] represent the effect of finite length of the plate in $x_{1}$ direction. They will vansh in this case since the plate has an infinite length in $x_{1}$ direction. Integral equations are written for only half of the infinite plate ( $x_{1}>0$ ) and are only valid when symmetry with respect to the $x_{2} x_{3}$ plane exists. $D$ represents the normalized cracked region on the $x_{1}$ axis, which means that if there is a crack in the region ( $b, c$ ), $D$ represents the region ( $b / a, c / a$ ) where ${ }^{\prime} a^{\prime \prime}$
is the half crack length and equals to (c-b)/2. $x$ is also normalized parameter on $x_{1}$ axis which is $x=x_{1} / a_{i}$, where $a_{i}$ the half crack length for the corresponding crack(i subscript is needed because general formulation is done for more than one crack).

From [15], integral equations are as follows:

$$
\begin{gather*}
\frac{\sigma(x)}{E}-\frac{1}{2 \pi} \int_{D}\left[\frac{1}{t-x}+\frac{1}{t+x}\right] G_{1}(t) d t=\frac{\sigma_{0}(x)}{E}, \quad x \in D,  \tag{1}\\
\frac{m(x)}{6 E}-R_{1} \int_{D}\left[R_{2}\left[\frac{1}{t-x}+\frac{1}{t+x}\right]-R_{3}\left[\frac{1}{(t-x)^{3}}+\frac{1}{(t+x)^{3}}\right]\right. \\
\left.\left.+\frac{1}{t-x} K_{2}(p|t-x|)+\frac{1}{t+x} K_{2}(p|t+x|)\right]\right] G_{2}(t) d t \\
=\frac{m_{0}(x)}{6 E}, \tag{2}
\end{gather*}
$$

where $R_{2}$ is the modified Bessel function of the second kind and the constants $R_{1}, R_{2}, R_{3}, R_{4}$ and $p$ are def ined in Appendix $I$. $h$ is the thickness of the plate, $2 a$ is the length and $L\left(x_{1}\right)$ is the depth of the crack (Fig. 1). E is the modulus of elasticity and $v$ is the Poisson's ratio of the material. The unknown functions are defined by

$$
\begin{align*}
& G_{1}(x)=\frac{\partial}{\partial x} E_{y}(x,+0), \quad G_{2}(x)=\frac{\partial}{\partial x} v(x,+0),  \tag{3}\\
& E_{y}=\varepsilon_{2}
\end{align*}, \quad \forall=u_{2} / a .
$$

The external loads

$$
\begin{equation*}
\sigma_{0}=\frac{N_{22}^{0}}{h}, \quad m_{0}=\frac{6 M_{22}^{0}}{h^{2}} \tag{4}
\end{equation*}
$$

represent uniform membrane and bending resultants applied to the plate away from the crack region and 5 and m which are defined by

$$
\begin{equation*}
\sigma(x)=\frac{N(x, 0)}{h}, \quad m(x)=\frac{6 M(x, 0)}{h^{2}}, \quad x \in D \tag{5}
\end{equation*}
$$

are the membrane and bending loads applied to the crack surfaces (Fig. 1). The integral equations are obtained from the following mixed boundary conditions in $x_{2}=0$ plane

$$
\begin{array}{ll}
N_{22}(x, 0)=-N_{22}^{0}+N(x) & , \\
u_{2}(x, 0)=0 & x \in D, \\
M_{22}(x, 0)=-M_{22}^{0}+M(x) & , \\
B_{2}(x, 0)=0 & x \in D,  \tag{7b}\\
& x \in D,
\end{array}
$$

where the general principle of superposition is used to account for the loading $N_{22}^{0}$, and $M_{22}^{0}$ applied to the structure away from the crack region.

### 2.2 Line-Spring Model for an Edge Crack

Edge crack is chosen for introductory purposes because of the simplicity of its formulation. Modifications will be made as more complicated crack geametries are examined.

The configuration studied here is an "infintte" elastic plate of thickness $h$, whach contains a surface crack of length $2 a$ and depth $L\left(x_{1}\right)$ penetrating part through the thickness (Fig. 1). For general purposes $L\left(x_{1}\right)$ can be any function which enables us to treat any crack geometry. At remote distances from the crack site, the plate is subjected to loads equppollent to a uniform sumple tension in the $x_{2}$ direction and to pure bending about the $x_{1}$ axis. The first
assumption in the linemsping analysis is that the stress intensity factor at a point along the crack front with coordinate $x_{\mathcal{1}}$ is identical to the stress intensity factor for an edge cracked strip in plane strain (Fig. 2), subjected to an axial force and monent equal, respectively, to $N_{22}\left(x_{1}, 0\right)$ and $M_{22}\left(x_{1}, 0\right)$, and having a crack depth equal to $L\left(x_{1}\right)$. In [1], [3], mode I stress intensity factor for the plane strain problem is given as

$$
\begin{align*}
& K(s)=\sqrt{h}\left[\sigma g_{t}(s)+\operatorname{mg}_{b}(s)\right]  \tag{8}\\
& s\left(x_{q}\right)=L\left(x_{q}\right) / h \tag{9}
\end{align*}
$$

where functions $g_{t}(s)$ and $g_{b}(s)$ are called shape functions for tension and bending respectively, and given as

$$
\begin{align*}
& g_{t}(s)=\sqrt{\pi s} \sum_{i=1}^{n} b_{i} s^{2(i-1)},  \tag{10a}\\
& g_{b}(s)=\sqrt{\pi s} \sum_{i=1}^{n} c_{i} s(i-1) \tag{10b}
\end{align*}
$$

The value of $n$ is chosen according to the desired accuracy. The coefficients $b_{i}$ and $c_{i}$ can be found by $a$ suitable curve fitting (Appendix II). Coefficients of the shape functions for a number of crack gequetries are given in Tables $2,4,6,8,10,12,14,16,17$.

In order to obtain $N\left(x_{1}\right)$ and $M\left(x_{1}\right)$ in terms of $G_{1}$ and $G_{2}$, the energy available for fracture along the crack front is expressed in two different ways, namely as the crack closure energy and as the product of load-load point displacement. In a plate with an edge crack subjected to uniform tension $N$ and uniform bending moment $M$ (Fig. 2), if $K$ is the stress intensity factor given by the plane strain solution, from the crack closure energy, the energy (per unit width) available for fracture may be obtained as

$$
\begin{equation*}
G=\frac{\partial}{\partial L}(U-V)=\frac{1-\nabla^{2}}{E} K^{2}, \tag{11}
\end{equation*}
$$

where $U$ is the work done by the external loads and $V$ is the strain energy.

Let $\delta$ and be the load line displacements corresponding to $N$ and $M$ shown in Fig. 2 and $d 8$ and $d 8$ be the changes in 8 and 8 as the crack length goes from $L$ to $L+d L$ under fixed load conditions. Then referring to Fig. 2, the changes in $U$ and $V$ may be expressed as

$$
\begin{align*}
\mathrm{dU} & =\mathrm{Nd} \delta+M \mathrm{~d} \theta,  \tag{12}\\
\mathrm{dV} & =(1 / 2)[N(\delta+d \delta)+M(\theta+d \theta)-(1 / 2)(N \delta+M B)= \\
& =(1 / 2)(N d \delta+M d \theta), \tag{13}
\end{align*}
$$

Equations (12) and (13) give the energy avallable for a crack growth dL as follows:

$$
\begin{equation*}
d(U-V)=(1 / 2)(N d \delta+M d d) . \tag{14}
\end{equation*}
$$

On the other hand for constant. $N$ and $M$, and for a change of $d L$ in the crack length, we have

$$
\begin{equation*}
d^{\delta}=\frac{\partial \delta}{\partial L} d L, \quad d \theta=\frac{\partial \theta}{\partial L} d L \quad . \tag{15}
\end{equation*}
$$

Thus, from (14) and (15) it follows that

$$
\begin{equation*}
\frac{\partial}{\partial L}(U-V)=G=\frac{1}{2}\left[N \frac{\partial \delta}{\partial L}+M \frac{\partial \varepsilon}{\partial L}\right] \tag{16}
\end{equation*}
$$

and, by using (11) we find

$$
\begin{equation*}
\frac{1}{2}\left[N \frac{\partial \delta}{\partial L}+M \frac{\partial \theta}{\partial L}\right]=\frac{1-\eta^{2}}{E} K^{2} \tag{17}
\end{equation*}
$$

From (5) and (8), we may rewrite (17) in terms of 6 and $m$ as

$$
\begin{equation*}
\frac{1}{2}\left[\sigma h \frac{\partial \delta}{\partial L}+m \frac{h^{2} \partial \varepsilon}{6} \frac{\varepsilon}{\partial L}\right]=h \frac{1-v^{2}}{E}\left(g_{t}^{2} s^{2}+2 g_{t} g_{b} \delta m+g_{b}^{2} m^{2}\right) \tag{18}
\end{equation*}
$$

In order to solve $\sigma$ and $m$ in terms of 5 and or vice versa we introduce the so called compliance coefficients. In a cracked strip, displacement and rotation are functions of both the applied stress and bending moment. This relation may be expressed as

$$
\begin{align*}
& \mathrm{h} \delta=A_{t t^{6}}+A_{t b^{m}},  \tag{19a}\\
& \mathrm{~h}^{2 \mathrm{e} / 6}=A_{\mathrm{b} t^{6}}+A_{b b^{m}}, \tag{19b}
\end{align*}
$$

where (with proper normalizations) $A_{t b}=A_{b t}$ by elastic reciprocity. The compliance coefficients $A_{i j}$ depend only on $L$ and vanish when L=0. If we substitute (19) into (18) and equate common coefficients in the quadratic forms of both sides, we get

$$
\begin{equation*}
\frac{d A_{t t}}{d L}=\frac{2\left(1-p^{2}\right) h}{E} g_{t}^{2} \tag{20a}
\end{equation*}
$$

$$
\begin{align*}
& \frac{d A_{t b}}{d L}=\frac{d A_{b t}}{d L}=\frac{2\left(1-v^{2}\right) h}{E} g_{t} g_{b},  \tag{20b}\\
& \frac{d A_{b b}}{d L}=\frac{2\left(1-v^{2}\right) h}{E} g_{b}^{2} . \tag{20c}
\end{align*}
$$

By defining

$$
\begin{equation*}
\alpha_{i j}=h^{-1} \int_{0}^{L} g_{i} g_{j} d L \quad, \quad(i, j=b, t) \tag{21}
\end{equation*}
$$

and knowing that $A_{i j}=0$ at $L=0$, we may write

$$
\begin{align*}
& A_{t t}=\frac{2 h^{2}\left(1-v^{2}\right)}{E} \alpha_{t t}  \tag{22a}\\
& A_{t b}=A_{b t}=\frac{2 h^{2}\left(1-v^{2}\right)}{E} \alpha_{t b},  \tag{22b}\\
& A_{b b}=\frac{2 h^{2}\left(1-v^{2}\right)}{E} \alpha_{b b} \tag{22c}
\end{align*}
$$

Substitution of (22) into (19) gives

$$
\begin{align*}
& \delta=\frac{2 h\left(1-\nabla^{2}\right)}{E}\left(\alpha_{t t}+\alpha_{t b^{m}}\right),  \tag{23}\\
& E=\frac{12\left(1-\nabla^{2}\right)}{E}\left(\alpha_{b t}+\alpha_{b b^{m}}\right), \tag{24}
\end{align*}
$$

where $\alpha_{t b}=\alpha_{b t}$. From (3), $\delta$ and 8 may be expressed in terms of the unknown functions $G_{1}$ and $G_{2}$ as

$$
\begin{align*}
& 6=2 B_{2}(x,+0)=2 \int_{-1}^{x} G_{1}(t) d t  \tag{25}\\
& 6=2 a u_{2}(x,+0)=2 a \int_{-1}^{x} G_{2}(t) d t . \tag{26}
\end{align*}
$$

If we solve (23) and (24) for $\sigma(x)$ and $m(x)$ and substitute (25) and (26) for $\delta$ and 6 , we can determine $\sigma(x)$ and $m(x)$ in terms of the unknown functions $G_{1}$ and $G_{2}$ as follows:

$$
\begin{equation*}
\sigma(x)=E\left[\boldsymbol{Y}_{t t}(x) \int_{-1}^{x} G_{2}(t) d t+\boldsymbol{Y}_{t b}(x) \int_{-1}^{x} G_{q}(t) d t\right], \tag{27}
\end{equation*}
$$

$$
\begin{equation*}
m(x)=6 E\left[\Psi_{b t}(x) \int_{-1}^{x} G_{2}(t) d t+\Psi_{b b}(x) \int_{-1}^{x} G_{1}(t) d t\right] \tag{28}
\end{equation*}
$$

where

$$
\begin{align*}
& r_{t t}=\frac{a}{h\left(1-p^{2}\right)} \frac{\alpha_{b b}}{\Delta}, \\
& r_{t b}=-\frac{1}{6\left(1-p^{2}\right)} \frac{\alpha_{t b}}{\Delta}, \\
& \boldsymbol{r}_{b t}=-\frac{1}{6 h\left(1-p^{2}\right)} \frac{\alpha_{b t}}{\Delta}, \\
& r_{b b}=\frac{1}{36\left(1-p^{2}\right)} \frac{\alpha_{t t}}{\Delta},  \tag{29d}\\
& \Delta=\alpha_{t t} \alpha_{b b}-\alpha_{t b}^{2} . \tag{29e}
\end{align*}
$$

We should keep in mind that $\alpha_{i j}$ is a function of $L(x) / h$, which means $\alpha_{i j}$ is also a function of $x$.

For a single crack shown in Fig. 1, the normalized cracked region on $x_{1}$ axds (called $D$ in (1) and (2)) is defined as ( 0,1 ). (1) and (2) then become

$$
\begin{gather*}
\frac{\sigma(x)}{E}-\frac{1}{2 \pi} \int_{0}^{1}\left[\frac{1}{t-x}+\frac{1}{t+x}\right] G_{1}(t) d t=\frac{\sigma_{0}}{E}, 0<x<1,  \tag{30}\\
+R_{4}\left[\frac{m(x)}{6 E}-R_{1} \int_{0}^{1}\left[R_{2} \frac{1}{t-x}+\frac{1}{t+x}-R_{3}\left[\frac{1}{(t-x)^{3}}+\frac{1}{(t+x)^{3}}\right]\right.\right. \\
=\frac{m_{0}}{6 E}, \quad 0<x<1 .
\end{gather*}
$$

For convenience in the numerical solution of integral equations we need to convert the integrals calculated over ( 0,1 ) to ( $-1,1$ ). Because of that the geometry and loading conditions are symmetric with respect to the $x_{2} x_{3}$ plane, $u_{2}(x,+0)$ and $\beta_{2}(x,+0)$ should al so be symmetric with respect to the same plane. In mathemathical form

$$
\begin{equation*}
u_{2}(-x,+0)=u_{2}(x,+0), \tag{32a}
\end{equation*}
$$

$$
\begin{equation*}
\xi_{2}(-x,+0)=\xi_{2}(x,+0) . \tag{32b}
\end{equation*}
$$

Observing that derivative of a symmetric function is antisymmetric, we may write

$$
\begin{align*}
& G_{1}(-t)=-G_{1}(t)  \tag{33a}\\
& G_{2}(-t)=-G_{2}(t) \tag{33b}
\end{align*}
$$

By applying the above properties, integrand of (30) can be rewritten as

$$
\begin{align*}
\int_{0}^{1}\left[\frac{1}{t-x}+\frac{1}{t+x}\right] G_{1}(t) d t & =\int_{0}^{1} \frac{1}{t-x} G_{1}(t) d t  \tag{34}\\
& +\int_{0}^{1} \frac{1}{t_{1}+x} G_{1}\left(t_{1}\right) d t_{1} .
\end{align*}
$$

By a change of variable $t_{1}=-t$ and from (33a), we can write

$$
\begin{align*}
\int_{0}^{1} \frac{1}{t_{1}+x} G_{1}\left(t_{1}\right) d t_{1} & =\int_{0}^{-1} \frac{1}{-t+x}\left[-G_{1}(t)\right](-d t) \\
& =\int_{-1}^{0} \frac{1}{t-x} G_{1}(t) d t \cdot \tag{35}
\end{align*}
$$

Substituting (35) in (34)

$$
\begin{equation*}
\int_{0}^{1}\left[\frac{1}{t-x}+\frac{1}{t+x}\right] G_{1}(t) d t=\int_{-1}^{1} \frac{1}{t-x} G_{q}(t) d t \tag{36}
\end{equation*}
$$

After applying the same procedure to (31) and substituting (27) and (28) for $S(x)$ and $m(x)$, integral equations take the following final form

$$
\begin{aligned}
& \boldsymbol{Y}_{b b}(x) \int_{-1}^{x} G_{q}(t) d t-R_{1} \int_{-1}^{1}\left[R_{2} \frac{1}{t-x}-R_{3} \frac{1}{(t-x)^{3}}\right. \\
& \left.+R_{4} \frac{1}{t-x} K_{2}(p|t-x|)\right] G_{1}(t) d t+\boldsymbol{Y}_{b t}(x) \int_{-1}^{x} G_{2}(t) d t \\
& -\quad=\frac{m_{0}}{6 E},-1<x<1,
\end{aligned}
$$

$$
\begin{align*}
Y_{t b}(x) & \int_{-1}^{x} G_{1}(t) d t+Y_{t t}(x) \int_{-1}^{x} G_{2}(t) d t \\
& =\frac{1}{2 T} \int_{-1}^{1} \frac{G_{2}(t)}{t-x} d t=\frac{\sigma_{0}}{E},-1<x<1 . \tag{37b}
\end{align*}
$$

From (3) it follows that the unknown functions $G_{1}$ and $G_{2}$ must satisfy the single valuedness conditions given by

$$
\begin{equation*}
\int_{-1}^{1} G_{1}(t) d t=0, \quad \int_{-1}^{1} G_{2}(t) d t=0 \tag{38}
\end{equation*}
$$

After solving (37) and (38) by using Gauss-Chebyshev closed type integration formula which is defined in Appendix III, a backward procedure is applied to find the stress intensity factors along the crack front. Unknown functions are integrated (Appendix IV) from -1 to the value of $x$ at which the stress intensity factor is desired. Then those integrals are substituted to (27) and (28) with the functions $\gamma_{i j}(x)$, (i, $\left.j=t, b\right)$ evaluated at that particular point to get corresponding $\sigma$ and $m$. Once $\sigma$ and $m$ are found, (8) gives the stress intensity factor at a specific point on the crack front.

### 2.3 Internal Cracks

The line-spring model described in the previous section may easily be extended to internal cracks such as that shown in Fig. 3. In this case the basic integral equations remain the same and again are given by (1) and (2). However, there are two crack tips (shown as $A$ and $B$ in Fig. 3) which create two different stress intensity factors for each cross-section taken perpendicular to $x_{q}$ direction. Previous assumptions regarding the stress intensity factors will also remain the same; however, they are now defined seperately, i. e.,

$$
\begin{align*}
& K_{A}=\sqrt{h}\left[\delta g_{A t}(s)+m g_{A b}(s)\right],  \tag{39a}\\
& K_{B}=\sqrt{h}\left[\delta g_{B t}(s)+m g_{B b}(s)\right], \tag{39b}
\end{align*}
$$

where $g_{A t}, g_{A b}$, $g_{B t}, g_{B b}$ are the shape functions corresponding to crack tips $A$ and $B$. Unlike the edge crack case, these shape functions are now functions of both $L\left(x_{j}\right) / h$ and $d / h$ where $d 2 s$ the distance from the center of the crack to the neutral plane. Two way
parametrization is needed in order to define the shape functions which are valid for any kind of internal crack. Since elliptic cracks whose major axis are parallel to the free surface are the main concern in the present study, parametrization can be simplified by observing that the distance between the center of any arack obtained by taking crossesections perpendicular to the major axis and the center line of the plate is fixed. In other words, $d$ is constant for any elliptic crack whose major axis is parallel to the free surface. Because of this property, as in the previous case, we may again define the shape functions for each crack as a function of only one variable, which is $L\left(x_{1}\right) / h$, as

$$
\begin{align*}
& \left.g_{A t}=\sqrt{T s} \sum_{i=1}^{n} b_{A i^{\prime}} s^{2(i-1}\right)  \tag{40a}\\
& g_{A b}=\sqrt{T s} \sum_{i=1}^{n} c_{A i} s^{i-1}  \tag{40b}\\
& g_{B t}=\sqrt{T s} \sum_{i=1}^{n} b_{B i} s^{2(i-1)}  \tag{40c}\\
& g_{B b}=\sqrt{T s} \sum_{i=1}^{n} c_{B i^{\prime}} s^{i-1} \tag{40d}
\end{align*}
$$

Keep in mind that coefficients are different for each value of $d$.

The next step is the representation of the energy available for fracture in terms of both stress intensity factors and product of load-load point displacement. As $L$ increases by dL, the energy
increment available for fracture may be expressed as

$$
\begin{equation*}
d(U-V)=\frac{1-r^{2}}{E}\left[K_{A}^{2} d(L / 2)+K_{B}^{2} d(L / 2)\right], \tag{41}
\end{equation*}
$$

giving

$$
\begin{equation*}
G=\frac{\partial}{\partial L}(U-V)=\frac{1-F^{2}}{2 E}\left(K_{A}^{2}+K_{B}^{2}\right) \tag{42}
\end{equation*}
$$

which replaces (11). The rate of energy available for fracture as expressed in terms of the load line displacements and forces remains the same and is given by (16). If the same procedure as in the previous section is followed, the functions $\boldsymbol{a}(i j)$ may be found as

$$
\begin{align*}
& \alpha_{t t}=h^{-1} \int_{0}^{L}\left(g_{A t}^{2}+g_{B t}^{2}\right) / 2 d L  \tag{43a}\\
& \alpha_{b b}=h^{-1} \int_{0}^{L}\left(g_{A b}^{2}+g_{B b}^{2}\right) / 2 d L  \tag{43b}\\
& \alpha_{t b}=\alpha_{b t}=h^{-1} \int_{0}^{L}\left(g_{A t} g_{A b}+g_{B t^{\prime}} g_{B b}\right) / 2 d L \tag{43c}
\end{align*}
$$

After this point, everything, including the resulting integral
equations and the solution method, is exactly the same as explained in Section 2.2. After solving the equations, the functions $G_{1}$ and $G_{2}$ are again substituted to (27) and (28) to $f$ ind 5 and $m$ which are then substituted to (39) to find the two stress intensity factors at the corresponding value of $x$.

### 2.4 Symmetric Internal Crack

This is a special case of an internal orack where d=0. Due to the fact that simple tension cannot create any crack surface rotation and simple bending cannot create any crack opening displacement (on the neutral plane), from (23) and (24) one can write

$$
\begin{equation*}
\boldsymbol{\alpha}_{t b}=\boldsymbol{\alpha}_{b t}=0 \tag{44}
\end{equation*}
$$

which gives

$$
\begin{equation*}
\Psi_{t b}=\boldsymbol{Y}_{b t}=0 \tag{45}
\end{equation*}
$$

Substitution of (45) into (37) would decouple the integral equations
(only unknown in (37a) is $G_{1}$ while the only unknown in (37b) is $G_{2}$ ) which would in turn enable us to solve them seperately. This property reduces both the computer time and memory space needed in the numerical solution.

### 2.5 Two Opposite Elliptic Edge Cracks

Two opposite edge cracks shown in Fig. 4 has exactly the same properties as symmetric internal cracks except for the coefficients of the shape functions. Once the shape functions are established by a suitable curve fitting, the same procedure that is applied to symmetric internal cracks is applied to find the stress intensity factors.

### 2.6 Interaction Between Two Identical Cracks

All the crack geometries that we considered up to now were single cracks lying in the region $(-a, a)$ on the $x_{1}$ axis. Only difference among them was their configuration in the thickness
direction. Shape functions, energy available for fracture and functions $\alpha_{i j}$ and $\mathcal{T}_{i j}$ are all sensitive to this configuration, while the form of the integral equation is independent of it. In this section, we will modify (1) and (2) for two identical cracks which is shown in Fig. 5. In this case $D$ is defined as (b/a, c/a). With the new definition of $D,(1)$ and (2) will take the following form.

$$
\begin{gather*}
\frac{\sigma\left(x^{\prime}\right)}{E}-\frac{1}{2 \pi} \int_{b^{\prime}}^{C^{\prime}}\left[\frac{1}{z-x^{\prime}}+\frac{1}{z+x^{\prime}}\right] G_{1}(z) d z=\frac{\sigma_{0}}{E}, b^{\prime}<x^{\prime}<c^{\prime}  \tag{46}\\
\frac{m\left(x^{\prime}\right)}{E}-R_{1} \int_{b^{\prime}}^{C^{\prime}}\left[R_{2}\left[\frac{1}{z-x^{\prime}}+\frac{1}{z+x^{\prime}}\right]-R_{3}\left[\frac{1}{\left(z-x^{\prime}\right)^{3}}+\frac{1}{\left(z+x^{\prime}\right)^{3}}\right]\right. \\
\left.+R_{4}\left[\frac{1}{z-x^{\prime}} K_{2}\left(p\left|z-x^{\prime}\right|\right)+\frac{1}{z+x^{\prime}} K_{2}\left(p\left|z+x^{\prime}\right|\right)\right]\right] G_{2}(z) d z \\
=\frac{m_{0}}{6 E} \quad, \quad b^{\prime}<x^{\prime}<c^{\prime}, \tag{47}
\end{gather*}
$$

where

$$
x^{\prime}=x_{1} / a, \quad b^{\prime}=b / a, \quad c^{\prime}=c / a
$$

Again we have to convert the limits of integrals to ( $-1,1$ ) for
numerical solution purposes. By introducing the following parameters (keep in mind that from Fig. 5, $\left(c^{\prime}-b^{\prime}\right) / 2=1$ )

$$
\begin{align*}
& x=\left(2 x^{\prime}-c^{\prime}-b^{\prime}\right) /\left(c^{\prime}-b^{\prime}\right),  \tag{48}\\
& x^{\prime}=\left[\left(c^{\prime}-b^{\prime}\right) x+c^{\prime}+b^{\prime}\right] / 2=x+\left[\left(c^{\prime}+b^{\prime}\right) / 2\right],  \tag{49}\\
& d x^{\prime}=d x \quad,
\end{align*}
$$

$t=\left(2 z-c^{\prime}-b^{\prime}\right) /\left(c^{\prime}-b^{\prime}\right)$,
$z=\left[\left(c^{\prime}-b^{\prime}\right) t+c^{\prime}+b^{\prime}\right] / 2=t+\left[\left(c^{\prime}+b^{\prime}\right) / 2\right]$,
$\mathrm{dz}=\mathrm{dt} \quad$,
and substituting (27) and (28) for $(x)$ and $m(x)$ respectively, (46) and (47) can be rewritten as follows:

$$
\begin{aligned}
& \boldsymbol{T}_{b b}(x) \int_{-1}^{x} G_{1}(t) d t-R_{1} \int_{-1}^{1}\left[R_{2}\left[\frac{1}{y_{1}}+\frac{1}{y_{2}}\right]-R_{3}\left[\frac{1}{y_{1}^{3}}+\frac{1}{y_{2}^{3}}\right]\right. \\
& \left.+R_{4}\left[\frac{1}{y_{1}} K_{2}\left(p\left|y_{1}\right|\right)+\frac{1}{y_{2}} K_{2}\left(p\left|y_{2}\right|\right)\right]\right] G_{1}(t) d t+Y_{b t}(x) \int_{-1}^{x} G_{2}(t) d t
\end{aligned}
$$

$$
\begin{gather*}
=\frac{m_{0}}{6 E} \quad,-1<x<1,  \tag{52}\\
r_{t b}(x) \int_{-1}^{x} G_{1}(t) d t+r_{t t}(x) \int_{-1}^{x} G_{2}(t) d t-\frac{1}{2 \pi} \int_{-1}^{1}\left[\frac{1}{y_{1}}+\frac{1}{y_{2}}\right] G_{2}(t) d t \\
 \tag{53}\\
=\frac{\sigma_{0}}{E} \quad,-1<x<1,
\end{gather*}
$$

where

$$
\begin{align*}
& y_{1}=t-x \\
& y_{2}=t+x+b^{\prime}+c^{\prime} \tag{54}
\end{align*}
$$

Integral equations (52) and (53) will again be solved by GaussChebyshev closed form integration formula with the additional conditions

$$
\begin{aligned}
& \int_{-1}^{1} G_{1}(t) d t=0 \\
& \int_{-1}^{1} G_{2}(t) d t=0
\end{aligned}
$$

and the same backward procedure defined in Section 2.2 is used to find stress intensity factors at any point on the crack defined in

#### Abstract

the region $(b, c)$. Due to symmetry with respect to the $x_{2} x_{3}$ plane, stress intensity factors on the two cracks are also symmetric with respect to the same plane. Integral equations are valid for any two identical crack (edge, internal, two opposite) problem providing the corresponding $y$ functions defined in Section 2.2 .

### 2.7 Interaction of Three Identical Cracks

As stated earlier integral equations for general case given in (1) and (2) are valid for any number of cracks provided there is symmetry with respect to the $x_{2} x_{3}$ plane. This means that any three crack system composed of a symmetric crack surrounded by two identical cracks (not needed to be identical with the third one) can be solved by using (1) and (2). But in this study, for simplification purposes, all of them are chosen identical. Configuration and parameters are shown in Fig. 6. D is defined as $(0,1),(b / a, c / a)$. Because of the nature of the problem, we expect that crack surface displacements and rotations be symmetric with respect to the $x_{2} x_{3}$ plane. This suggests that two outer cracks should have the same rotation and displacement at the equidistant points from the origin, while the third one undergoes completely different displacement and rotation. For this reason $G$ functions
should be defined seperately for inner crack and two outer cracks. Let

$$
\left.\left.\left.\begin{array}{rl}
G_{11}: & \text { Crack surface rotation derivative for } \\
& \text { the inner crack, }(-a, a),
\end{array}\right\} \begin{array}{rl}
G_{12}: & \text { Crack opening displacement derivative for } \\
& \text { the inner crack, }(-a, a),
\end{array}\right\} \begin{array}{rl}
G_{21}: & \text { Crack surface rotation derivative for } \\
& \text { the outer crack, }(b, c),
\end{array}\right\}
$$

Also $\sigma(x)$ and $m(x)$ for the inner and outer cracks should be defined seperately as follows,

$$
\begin{aligned}
& \sigma_{1}(x): \sigma(x) \text { for inner crack, } \\
& m_{1}(x): m(x) \text { for inner crack, } \\
& \sigma_{2}(x): \sigma(x) \text { for outer crack, } \\
& m_{2}(x): m(x) \text { for outer crack. }
\end{aligned}
$$

(1) and (2) can be written for inner crack

$$
\frac{\sigma_{1}\left(x^{\prime}\right)}{E}-\frac{1}{2 \pi} \int_{0}^{1}\left[\frac{1}{z-x^{\prime}}+\frac{1}{z+x^{\prime}}\right] G_{11}(z) d z-\frac{1}{2 \pi} \int_{\dot{b}}^{c^{\prime}}\left[\frac{1}{z-x^{\prime}}\right.
$$

$$
\begin{align*}
& \left.+\frac{1}{z+x^{\prime}}\right] G_{12}(z) d z=\frac{\sigma_{0}}{E}, 0<x^{\prime}<1,  \tag{55}\\
\frac{m_{1}\left(x^{\prime}\right)}{6 E} & -R_{1} \int_{0}^{1}\left[R_{2}\left[\frac{1}{z-x^{\prime}}+\frac{1}{z+x^{\prime}}\right]-R_{3}\left[\frac{1}{\left(z-x^{\prime}\right)^{3}}+\frac{1}{\left(z+x^{\prime}\right)^{3}}\right]\right. \\
& \left.+R_{4}\left[\frac{1}{z-x^{\prime}} K_{2}\left(p z^{\prime} x^{\prime}\right)+\frac{1}{z+x^{\prime}} K_{2}\left(p z^{\prime}+x^{\prime}\right)\right]\right] G_{12^{\prime}(z) d z} \\
& -R_{1} \int_{b^{\prime}}^{c^{\prime}}\left[R_{2}\left[\frac{1}{z-x^{\prime}}+\frac{1}{z+x^{\prime}}\right]-R_{3}\left[\frac{1}{\left(z-x^{\prime}\right)^{3}}+\frac{1}{\left(z+x^{\prime}\right)^{3}}\right]\right. \\
& \left.+R_{4}\left[\frac{1}{z-x^{\prime}} R_{2}\left(p\left|z-x^{\prime}\right|\right)+\frac{1}{z+x^{\prime}} K_{2}\left(p\left|z+x^{\prime}\right|\right)\right]\right] G_{22}(z) d z \\
& =\frac{m_{0}}{6 E} \quad 0<x^{\prime}<1, \tag{56}
\end{align*}
$$

and for outer crack

$$
\begin{align*}
& \frac{\sigma_{2}\left(x^{\prime}\right)}{E}-\frac{1}{2 \pi} \int_{0}^{1}\left[\frac{1}{z-x^{\prime}}+\frac{1}{z+x^{\prime}}\right] G_{11}(z) d z-\frac{1}{2 \pi} \int_{b^{\prime}}^{c^{\prime}}\left[\frac{1}{z-x^{\prime}}\right. \\
& \left.\quad+\frac{1}{z+x^{\prime}}\right] G_{12^{\prime}}(z) d z=\frac{\sigma_{0}}{E}, \quad b^{\prime}<x^{\prime}<c^{\prime}, \tag{57}
\end{align*}
$$

$$
\begin{align*}
& \frac{m_{2}\left(x^{\prime}\right)}{6 E}-R_{1} \int_{0}^{1}\left[R_{2}\left[\frac{1}{z-x^{\prime}}+\frac{1}{z+x^{\prime}}\right]-R_{3}\left[\frac{1}{\left(z-x^{\prime}\right)^{3}}+\frac{1}{\left(z+x^{\prime}\right)^{3}}\right]\right. \\
&\left.+R_{4}\left[\frac{1}{z-x^{\prime}} K_{2}\left(p\left|z-x^{\prime}\right|\right)+\frac{1}{z+x^{\prime}} K_{2}\left(p\left|z+x^{\prime}\right|\right)\right]\right] G_{12}(z) d z \\
&-R_{1} \int_{b^{\prime}}^{c^{\prime}}\left[R_{2}\left[\frac{1}{z-x^{\prime}}+\frac{1}{z+x^{\prime}}\right]-R_{3}\left[\frac{1}{\left(z-x^{\prime}\right)^{3}}+\frac{1}{\left(z+x^{\prime}\right)^{3}}\right]\right. \\
&\left.+R_{4}\left[\frac{1}{z-x^{\prime}} K_{2}\left(p\left|z-x^{\prime}\right|\right)+\frac{1}{z+x^{\prime}} K_{2}\left(p\left|z+x^{\prime}\right|\right)\right]\right] G_{22^{\prime}}(z) d z \\
&=\frac{m_{0}}{6 E}, b^{\prime}<x^{\prime}<c^{\prime}, \tag{58}
\end{align*}
$$

where $x^{\prime}=x / a, b^{\prime}=b / a, c^{\prime}=c / a$.

From (36), we may write

$$
\begin{align*}
& \int_{0}^{1}\left[\frac{1}{z-x^{\prime}}+\frac{1}{z+x^{\prime}}\right] G_{11}(z) d z=\int_{-1}^{1} \frac{1}{z-x^{\prime}} G_{11}(z) d z  \tag{59}\\
& \int_{0}^{1}\left[R _ { 2 } \left[\frac{1}{z-x^{\prime}}+\frac{1}{z+x^{\prime}}-R_{3}\left[\frac{1}{\left(z-x^{\prime}\right)^{3}}+\frac{1}{\left(z+x^{\prime}\right)^{3}}\right]+R_{4}\left[\frac{1}{z-x^{\prime}} K_{2}\left(p\left|z-x^{\prime}\right|\right)\right.\right.\right.
\end{align*}
$$

$$
\begin{align*}
& \left.\left.+\frac{1}{z+x^{\prime}} K_{2}\left(p\left|z+x^{\prime}\right|\right)\right]\right] G_{12}(z) d z=\int_{-1}^{1}\left[R_{2} \frac{1}{z-x^{\prime}}-R_{3} \frac{1}{\left(z-x^{\prime}\right)^{3}}\right. \\
& \left.+R_{4} \frac{1}{z-x^{\prime}} K_{2}\left(p\left|z-x^{\prime}\right|\right)\right] G_{12}(z) d z \tag{60}
\end{align*}
$$

Same expressions as (59) and (60) can also be written for $G_{21}$ and $\mathrm{G}_{22}$.

If we define

$$
\begin{array}{lll}
x^{\prime}=x & \text { for } & -1<x^{\prime}<1 \\
z=t & \text { for } & -1<z<1
\end{array}
$$

and use (49) and (51) for $b^{\prime}<x^{\prime}<c^{\prime}$ and $b^{\prime}<z<c^{\prime}$ respectively, and substitute (27), (28) for $\sigma(x)$ and $m(x)$, (55), (56), (57), (58) will take the following final form

$$
\begin{aligned}
& \boldsymbol{r}_{b b}(x) \int_{-1}^{x} G_{21}(t) d t-R_{1} \int_{-1}^{1}\left[R_{2}\left[\frac{1}{y_{1}}+\frac{1}{y_{2}}\right]-R_{3}\left[\frac{1}{y_{1}^{3}}+\frac{1}{y_{2}^{3}}\right]\right. \\
& \left.\quad+R_{4}\left[\frac{1}{y_{1}} K_{2}\left(p\left|y_{1}\right|\right)+\frac{1}{y_{2}} K_{2}\left(p\left|y_{2}\right|\right)\right]\right] G_{21}(t) d t-R_{1} \int_{-1}^{1}\left[R_{2} \frac{1}{y_{3}}\right.
\end{aligned}
$$

$$
\begin{align*}
& \left.-R_{3} \frac{1}{y_{3}^{3}}+R_{4} \frac{1}{y_{3}} K_{2}\left(p\left|y_{3}\right|\right)\right] G_{11}(t) d t+Y_{b t}(x) \int_{-1}^{x} G_{22}(t) d t \\
& =\frac{m_{0}}{6 E} \quad, \quad-1<x<1,  \tag{61}\\
& T_{t b}(x) \int_{-1}^{x} G_{21}(t) d t+Y_{t t}(x) \int_{-1}^{x} G_{22}(t) d t-\frac{1}{2 \pi} \int_{-1}^{1}\left[\frac{1}{y_{1}}\right. \\
& \left.+\frac{1}{y_{2}}\right] G_{22}(t) d t-\frac{1}{2 \pi} \int_{-1}^{1} \frac{1}{y_{3}} G_{12}(t) d t=\frac{c_{0}}{E},-1<x<1 \text {, }  \tag{62}\\
& \underline{\boldsymbol{Y}}_{b b}(x) \int_{-1}^{x} G_{11}(t) d t-R_{1} \int_{-1}^{1}\left[R_{2}\left[\frac{1}{y_{4}}+\frac{1}{y_{5}}\right]-R_{3}\left[\frac{1}{y_{4}^{3}}+\frac{1}{y_{5}^{3}}\right]\right. \\
& \left.+R_{4}\left[\frac{1}{y_{4}} K_{2}\left(p y_{4}\right)+\frac{1}{y_{5}} K_{2}\left(p y_{5}\right)\right]\right] G_{21}(t) d t-R_{1} \int_{-1}^{1}\left[R_{2} \frac{1}{y_{1}}\right. \\
& \left.-R_{3} \frac{1}{y_{1}^{3}}+R_{4} \frac{1}{y_{1}} K_{2}\left(p y_{1}\right)\right] G_{11}(t) d t+X_{b t}(x) \int_{-1}^{x} G_{12}(t) d t \\
& =\frac{m_{0}}{6 E} \quad, \quad-1<x<1, \\
& \boldsymbol{r}_{t b}(x) \int_{-1}^{x} G_{11}(t) d t+\boldsymbol{r}_{t t}(x) \int_{-1}^{x} G_{12}(t) d t-\frac{1}{2 \pi} \int_{-1}^{1}\left[\frac{1}{y_{4}}\right.
\end{align*}
$$

$$
\begin{equation*}
\left.+\frac{1}{y_{5}}\right] G_{22}(t) d t-\frac{1}{2 \pi} \int_{-1}^{1} \frac{1}{y_{1}} G_{12}(t) d t=\frac{c_{0}}{E},-1<x<1, \tag{64}
\end{equation*}
$$

where

$$
\begin{aligned}
& y_{1}=t-x \\
& y_{2}=t+x+b^{\prime}+c \\
& y_{3}=t-x-\left[\left(b^{\prime}+c^{\prime}\right) / 2\right] \\
& y_{4}=t+x+\left[\left(b^{\prime}+c^{\prime}\right) / 2\right] \\
& y_{5}=t-x+\left[\left(b^{\prime}+c^{\prime}\right) / 2\right]
\end{aligned},
$$

This problem has four integral equations, (61), (62), (63), (64), with four unknown functions, $G_{11}, G_{12}, G_{21}, G_{22}$, which will be solved by Gauss-Chebyshev closed type integration formula under the following single-valuedness conditions.

$$
\begin{aligned}
& \int_{-1}^{1} G_{19}(t) d t=0 \\
& \int_{-1}^{1} G_{12}(t) d t=0 \\
& \int_{-1}^{1} G_{21}(t) d t=0 \\
& \int_{-1}^{1} G_{22}(t) d t=0
\end{aligned}
$$

After solving for the unknown functions, the same bacloward procedure
defined in Section 2.2 will be used for each crack seperately in order to find stress intensity factors.

Provided the corresponding $\mathcal{Y}$ functions, equations (61), (62), (63), (64) can be applied to any type(edge, internal, collinear) of identical cracks. The only reason for considering identical cracks to demonstrate interaction of three cracks in this section is simplicity. Line-spring model can also be applied to any three crack system which has two outer identical cracks with another symmetric(with respect to the $x_{2} x_{3}$ plane) crack in the middle. In this case, $\boldsymbol{T}$ functions and crack length will be defined seperately for both(outer ones and inner one) cracks. One should keep in mind that crack length is a parameter in the coefficients of (61), (62), (63), (64). Attention must be paid to redifine the coefficients in such case.

There are two main objectives in this study:

1. Assess the accuracy of line spring model,
2. Provide extensive numerical results which may be useful in application.

Due to unavailability of the solutions for the cases that we are interested in, the first objective can only be reached for the central ( $\mathrm{d} / \mathrm{h}=0$ ) elliptic internal crack under pure tension. Extensive results for central, eccentric internal cracks and two opposite edge cracks as well as the interaction among two and three cracks are tabulated. In all cases it was assumed that $\boldsymbol{V}=0.3$. However, the effect of $p$ on the stress intensity factors does not seem to be significant.

First step for the application of line spring model is to represent the SIFs as a polynomial in $\mathrm{L} / \mathrm{h}$. For this purpose, extensive information about plane strain (a/Lo ) stress intensity factors are needed. These results are obtained from previous materials for internal cracks, from [18] for two opposite edge cracks and are tabulated in Tables 1,3,5,7,9,11,13,15. Corresponding coefficients of shape functions are tabulated in Tables $2,4,6,8,10,12,14,16$. Coefficients of shape functions for the edge crack case are directly taken from [1] and tabulated in Table 17.

As noted before, for the application of the line spring model, the contour of the part-through crack can be any reasonable curve. Elliptic cracks are studied here since it is believed that ellipse is the closest contour for the actual shape of the crack which may be encountered in practical applications. Thus, crack length for any cross section is defined by,

$$
L\left(x_{1}\right)=L_{0} \sqrt{1-\left(x_{1} / a\right)^{2}}=L_{0} \sqrt{1-x^{2}}
$$

$L_{0}$ being the total crack length at the midsection $(x=0)$. Note that the limiting values of the SIF are

$$
K \rightarrow 0 \text { for } a / h \rightarrow 0 ; K \rightarrow K_{\infty} \text { for } a / h \rightarrow \infty
$$

The first case that is studied is the central internal elliptic crack (d/h=0). Extensive results and formulas developed from a finite element method for this case are given in [19]. Table 18 and Figs. 19,20 show the comparision of the SIFs obtained from this study with those generated from the formulas given in [19]. SIFs obtained from [19] are represented as $K^{r}$ while the normalizing SIF is $K_{0}=\sigma_{0} \sqrt{\pi L_{0} / 2}$ where $\sigma_{0}=N_{22}^{\infty} / h$. Both values and the percent differences between them are given for various parameters at $x=0$ and $x=1 / 2$. As expected, the SIFs $K\left(L_{0}\right)$ for the elliptic crack are
consistently smaller than the plane strain values. The table shows that with the exception of relatively small values of $a / L_{0}$ at small $L_{0} / h$ (for which the line spring is really not a suitable model) the agreement is surprisingly good. From the results, one may conclude that line spring can be used with some confidence for any central internal elliptic crack which has an $a / L_{0}$ ratio larger than 2.

SIFs for the same geometry, but under pure bending are given in Table 20 (Fig. 21). This time, normalizing SIF is defined as $K_{0}=m_{0}\left(\pi L_{0} / 2\right)^{1 / 2}$ where $m_{0}=6 M_{22}^{00} / h$. The results given are for the tension side. On the compression side the stress intensity factors have the same values with a negative sign. Under pure bending, since the crack faces on the compression side of the plate would close, the results given in the table cannot be used seperately. The results are, of course, useful and valid if the plate is subjected to tension, as well as bending, in such a way that the superimposed SIF is positive everywhere.

From Table 20 , by excluding the case of $a / L_{0}=0.5$ which proved to be unreliable, it may be concluded that SIF are independent of $a / L_{0}$ ratio for $L_{0} / h<0.5$. For $L_{0} / h>0.5$, SIF begins to increase with increasing $L_{o} / h$ ratio, which is expected. Though we are unable to confirm the accuracy of the line spring model in this case, we could say that there is no unusual behaviour in the results. Results are asymptotically approaching to plane strain values as $a / L_{o}$ is

Increased except for large $L_{o} / h$ values.

Another comparision with the previous finite element results [20] is shown in Table 19 (Fig. 23). It should be noted that in the results given in Table $19 \mathrm{a} / L_{0}=1.25$ is relatively small for the line spring model to be effective. Despite that, the relative error does not seem to be very high.

After symmetric internal cracks, nonsymmetrically located internal cracks are studied both under pure tension and pure bending conditions. Extensive results which scan almost all possible configurations are given in Tables 21-32 (Figs. 7-18). Normalizing SIFs are the same as that defined in the previous case for both tension and bending. Again we are unable to verify in which region the line spring results are reliable because of the lack of previous work done on this kind of problem. Asymptotic convergence to plane strain results is fairly good. A close observation of the tension results would show that for small a/Lo ratios SIFs first decrease, then increase with increasing $L_{0} / h$. This is mainly due to the fact that tabulated results are normalized with respect to $c_{0} \sqrt{\pi L_{0} / 2}$. Thus, even though the normalized SIF is decreasing, the real SIF may increase (which indeed happens in this case) but with a lower rate than the rate of increase of $L_{0}$. Also, again for small $L_{0} / h$ and $a / L_{0}$ values $S I F$ on the inside part of the crack front turns out to be greater than that on the other part of the crack border which is
closer to the free surface.

Two opposite elliptic edge cracks have been studied only under pure tension. Normalizing stress intensity factor is again $\sigma_{0}\left(\operatorname{Ti}_{0} / 2\right)^{1 / 2}$ with $\sigma_{0}=N_{22^{\prime}}^{\infty} / h$. Decreasing-increasing behaviour of the SIFs is again observed here. Same explanation which is given earlier is also valid for this case. Plane strain results are very close to each other in the region that we observe the slight decrease in SIFs. For this reason, a small uncertainity in the calculations can easily result with a slight decrease while we are expecting a slight increase. Except this behaviour, everything is as expected in Table 33 (Fig. 22).

Results for the interaction of two identical elliptic internal cracks under pure bending and pure tension have been tabulated in Tables 34 and 35 respectively. It can be seen that there is almost no interaction between two identical elliptic edge cracks if the distance between them (Fig. 5) is larger than 8 times the half crack length, a. Another result which may be observed is that the interaction is more effective for the cracks having large $L_{0} / h$ ratios.

SIFs for the two identical central internal elliptic cracks are tabulated in Table 36. Results are given only for tension case because it has been observed that there is no appreciable
interaction for the crack geometries given in Table 36 under pure bending. SIF deviates not more than $1 \%$ from the single crack value for $b / a=0.1$ in bending. It is seen that as the distance between the two cracks is increased the single crack solution is easily recovered. There is almost mo interaction for $b / a \geqslant 0.1$ for the cracks $L_{0} / h<0.5$. If $L_{0} / h>0.5$, no interaction region can be defined for $b / a \geqslant 4$.

Interaction results for any two identical elliptic internal cracks are given in Table 37. Some erratic results are observed for small $a / L_{0}$ ratios at small $L_{0} / h$ ratios. Glearly, for these ark geametries line spring is not a suitable model.

As the last example, SIFs for the three identical internal elliptic cracks under pure tension are calculated and are given in Table 38. The only conclusion one may draw from these results is that the SIFs on the middle crack are slightly higher than the SIFs on the outer crack. But the difference is so small that they may be regarded as equal.

TABLES

Table 1. Stress intensity factors for centrally cracked plate subjected to tension $N$ or bending $M$ under plane strain conditions.

| $L / h$ | $\left(K / K_{0}\right)_{N}$ | $\left(K / K_{0}\right)_{M}$ |

## APPENDIX I

The dimensionless quantities used in the formulation:

$$
\begin{aligned}
& x=\frac{x_{1}}{a_{1}}, \quad y=\frac{x_{2}}{a_{i}}, \quad z=\frac{x_{3}}{a_{i}}, \\
& u=\frac{u_{1}}{a_{i}}, \quad v=\frac{u_{2}}{a_{i}}, \quad w=\frac{u_{3}}{a_{i}}, \\
& \boldsymbol{\beta}_{x}=\beta_{1}, \quad \beta_{y}=\beta_{2}, \\
& \lambda^{4}=12\left(1-v^{2}\right) \frac{a_{i}^{2}}{h^{2}}, \\
& p=\left[\frac{2}{x(1-v)},\right. \\
& R_{1}=\frac{a_{i}\left(1-v^{2}\right)}{2 \pi h \lambda^{4}}, \\
& R_{3}=\frac{h^{2}}{5(1-v) a_{i}^{2}}, \\
& \frac{1+v)}{v(1-v)},
\end{aligned}
$$

## APPENDIX II

Procedure for finding coefficients of the shape functions ( $g_{t}$ and $g_{b}$ ) are as follows. Loading should be seperated as pure tension and pure bending. For pure tension case

$$
m=0
$$

By using (8), (9) and (10a)

$$
\begin{aligned}
& K(s)=\sqrt{h} \odot g_{t}(s), \\
& K(s)=\sqrt{h} \odot \sqrt{\pi s} \sum_{i=1}^{n} b_{i}(s)^{2(i-1)}, \\
& K(s)=\sigma \sqrt{\pi L\left(x_{1}\right)} \sum_{i=1}^{n} b_{i}(s)^{2(i-1)}, \\
& \frac{K(s)}{\sigma \sqrt{\pi L\left(x_{1}\right)}}=\sum_{i=1}^{n} b_{i}(s)^{2(i-1)}
\end{aligned}
$$

Values of the left handside can easily be found for a wide range of $s$ values in related iiterature, which enables us to create $n$ equations with $b_{i}$ 's as the $n$ unknowns. Solution of this system is the coefficient of corresponding shape function.

Same procedure is followed under pure bending to find $c_{i}$ 's.

## Solution of the Integral Equations

## i- Gauss-Chebyshev Closed Type Integration Formula

The solution of the integral equation which only has the Cauchy type singularity

$$
\frac{1}{\pi} \int_{-1}^{1} \frac{\phi(t)}{t-x} d t+\int_{-1}^{1} k(x, t) \phi(t) d t=f(x),-1<x<1,
$$

may be expressed as

$$
\begin{aligned}
& \phi(t)=\left(1-t^{2}\right)^{-1 / 2} g(t) \\
& K(x, t)=\frac{1}{\pi} \frac{1}{t-x}+k(x, t)
\end{aligned}
$$

$$
\begin{array}{r}
\frac{\pi}{n-1}\left[\frac{1}{2} K\left(x_{j}, t_{1}\right) g\left(t_{1}\right)+\sum_{i=2}^{n-1} K\left(x_{j}, t_{i}\right) g\left(t_{i}\right)+\frac{1}{2} K\left(x_{j}, t_{n}\right) g\left(t_{n}\right)\right] \\
=f\left(x_{j}\right) \quad, \quad j=1, \ldots \ldots,(n-1)
\end{array}
$$

$$
t_{i}=\cos \left[\frac{i-1}{n-1} \pi\right], \quad i=1, \ldots \ldots, n
$$

$$
x_{j}=\cos \left[\frac{2 j-1}{2 n-2} \pi\right], \quad j=1, \ldots \ldots,(n-1)
$$

and the additional condition

$$
\int_{-1}^{1}(t) d t=A
$$

becomes

$$
\frac{\pi}{n-1}\left[\frac{1}{2} g\left(t_{1}\right)+\sum_{i=2}^{n-1} g\left(t_{i}\right)+\frac{1}{2} g\left(t_{n}\right)\right]=A
$$

One may find the detailed derivation of the formula in [4].

When there is a system of integral equations with more than one unknown functions to be solved, the above procedure can be used by applying the formula to each integration seperately. For example

$$
\begin{aligned}
& \frac{1}{\pi} \int_{-1}^{1} \frac{\Phi_{1}(t)}{t-x} d t+\int_{-1}^{1} k_{11}(x, t) \phi_{1}(t) d t \\
& \\
& +\int_{-1}^{1} k_{12}(x, t) \omega_{2}(t) d t=f_{1}(x), \\
& \int_{-1}^{1} k_{21}(x, t) \omega_{1}(t) d t+\int_{-1}^{1} k_{22}(x, t) \omega_{2}(t) d t \\
& \\
& \\
& +\frac{1}{\pi} \int_{-1}^{1} \frac{t_{2}(t)}{t-x} d t=f_{2}(x)
\end{aligned}
$$

$$
\int_{-1}^{1} \phi_{1}(t) d t=A_{1}, \quad \int_{-1}^{1} \phi_{2}(t) d t=A_{2}, \quad-1<x<1
$$

can be solved as

$$
\begin{aligned}
& \phi_{1}(t)=\left(1-t^{2}\right)^{-1 / 2} g_{1}(t), \\
& \phi_{2}(s)=\left(1-s^{2}\right)^{-1 / 2} g_{2}(s),
\end{aligned}
$$

$s$ has been introduced to affine different collocation points for each functions.

$$
\begin{aligned}
& K_{11}(x, t)=\frac{1}{\pi} \frac{1}{t-x}+k_{11}(x, t) \\
& K_{12}(x, s)=k_{12}(x, s) \\
& K_{21}(x, s)=k_{21}(x, s) \\
& K_{22}(x, s)=\frac{1}{\pi} \frac{1}{s-x}+k_{22}(x, s)
\end{aligned}
$$

$$
\begin{aligned}
& \frac{T}{n_{1}-1}\left[\frac{1}{2} K_{11}\left(x_{j}, t_{1}\right) g_{1}\left(t_{q}\right)+\sum_{i=2}^{n_{-1}-1} K_{11}\left(x_{j}, t_{i}\right) g_{1}\left(t_{i}\right)+\frac{1}{2} K_{11}\left(x_{j}, t_{n 1}\right) g_{1}\left(t_{n 1}\right)\right] \\
& +\frac{\pi}{n_{2}-1}\left[\frac{1}{2} K_{12}\left(x_{j}, s_{1}\right) g_{2}\left(s_{1}\right)+\sum_{i=2}^{n_{2}-1} K_{12}\left(x_{j}, s_{i}\right) g_{2}\left(s_{i}\right)\right. \\
& \left.+\frac{1}{2} K_{12}\left(x_{j}, s_{n 2}\right) g_{2}\left(s_{n 2}\right)\right]=f_{2}\left(x_{j}\right) \text {, } \\
& x_{j}=\cos \left[\frac{2 j-1}{2 n_{1}-2} \pi\right], \quad j=1, \ldots \ldots,\left(n_{1}-1\right) \\
& \frac{\pi}{n_{1}-1}\left[\frac{1}{2} K_{21}\left(x_{j}, t_{1}\right) g_{1}\left(t_{1}\right)+\sum_{i=2}^{n_{1}-1} K_{21}\left(x_{j}, t_{i}\right) g_{1}\left(t_{i}\right)+\frac{1}{2} K_{21}\left(x_{j}, t_{n 1}\right) g_{1}\left(t_{n 1}\right)\right] \\
& +\frac{\pi}{n_{2}-1}\left[\frac{1}{2} K_{22}\left(x_{j}, s_{1}\right) g_{2}\left(s_{1}\right)+\sum_{i=2}^{n_{2}-1} K_{22}\left(x_{j}, s_{i}\right) g_{2}\left(s_{i}\right)\right. \\
& \left.+\frac{1}{2} K_{22}\left(x_{j}, s_{n 2}\right) g_{2}\left(s_{n 2}\right)\right]=f_{2}\left(x_{j}\right) \\
& x_{j}=\cos \left[\frac{2 j-1}{2 n_{2}-2} \pi\right], \quad j=1, \ldots \ldots,\left(n_{2}-1\right) \\
& \frac{\pi}{n_{1}-1}\left[\frac{1}{2} g_{1}\left(t_{1}\right)+\sum_{i=2}^{n_{1}-1} g_{1}\left(t_{2}\right)+\frac{1}{2} g_{1}\left(t_{n 1}\right)\right]=A_{1}, \\
& \frac{\pi}{n_{2}-1}\left[\frac{1}{2} g_{2}\left(s_{1}\right)+\sum_{i=2}^{n_{2}-1} g_{2}\left(s_{i}\right)+\frac{1}{2} g_{2}\left(s_{n 2}\right)\right]=A_{2},
\end{aligned}
$$

$$
\begin{aligned}
& t_{i}=\cos \left[\frac{i-1}{n_{1}-1} \pi\right], \quad i=1, \ldots \ldots, n_{1} \\
& s_{i}=\cos \left[\frac{i-1}{n_{2}-1} \pi\right], \quad i=1, \ldots \ldots, n_{2}
\end{aligned}
$$

Above solution can also be used for any number of unknown functions in the same manner.
ii- Order of Singularity in the Integral Equation

At.first glance, it seems that (31) has singularities other than Cauchy type. But if we take a closer look to the equation, we will see that modified Bessel function of the second kind has the following property for relatively small values of the argument.

$$
\begin{aligned}
& K_{r}(x) \sim 2^{r-1}(r-1)!x^{-r} \\
& K_{2}(x) \sim 2 x^{-2}
\end{aligned}
$$

By using above property, we can say that

$$
\lim _{(t-x) \rightarrow 0} K_{2}(p|t-x|)=\frac{2}{p^{2}(t-x)^{2}}=\frac{K(1-p)}{(t-x)^{2}}
$$

$$
\lim _{(t-x) \rightarrow 0}\left[\frac{4}{1+p} \frac{1}{t-x} K_{2}(p|t-x|)-\frac{4 k(1-\infty)}{1+p} \frac{1}{(t-x)^{3}}\right]=0
$$

This proves that (31) has only Cauchy type singularity and can be sol ved by Gauss-Chebyshev closed type integration formula.

Integrals on the interval $(-1, x)$ can be written on $(-1,+1)$ by redifining the kernels by the use of a step function $H(y)$ as follows:

$$
\int_{-1}^{x} f(t) d t=\int_{-1}^{1} H(x-t) f(t) d t
$$

where,

$$
H(y)=\left\{\begin{array}{lll}
0 & \text { if } & y<0 \\
1 & \text { if } & y \geqslant 0
\end{array}\right.
$$

## APPENDIX I

```
    Numerical Integration
    Gauss-Chebyshev closed type integration formula is used for
numerical integration purposes. Any integral in the interval
(-1 , +1) can be expressed as,
    < }\frac{f(x)dx}{\sqrt{}{1-\mp@subsup{x}{}{2}}}=\frac{\pi}{n-1}[\frac{1}{2}f(\mp@subsup{x}{1}{})+\mp@subsup{\sum}{i=2}{n-1}f(\mp@subsup{x}{1}{})+\frac{1}{2}f(\mp@subsup{x}{n}{})
```

    If an integration in the interval \((-1, x)\) is desired, above formula can again be used by multiplyang the integrand with the \(H\) function defined in Appendix III.
    Number of points ( $n$ ) in the integration should be much hagher than the number of points used in the solution of integral equations if one desires to evaluate the stress intensity factor or the crack front at any point accurately. Vilues of the functions to be integrated at any point can be found by interpolating the function between the two surrounding known values found from the solution of integral equations.

## End of Document
