$$^{\circ}\text{F} = (1.8 \times ^{\circ}\text{C}) + 32.$$

Datum

Horizontal coordinate information is referenced to the North American Datum of 1983 (NAD 83), unless otherwise specified.

Supplemental Information

Specific conductance is given in microsiemens per centimeter at 25 degrees Celsius ($\mu\text{S}/\text{cm}$ at 25°C). Concentrations of chemical constituents in water are given in either milligrams per liter (mg/L), micrograms per liter ($\mu\text{g}/\text{L}$), or nanograms per liter (ng/L).

Concentrations of chemical constituents in sediment and fish tissue are given in either milligrams per gram (mg/g), micrograms per gram ($\mu\text{g}/\text{g}$), nanograms per gram (ng/g), picograms per gram (pg/g), or micromoles per gram ($\mu\text{mol}/\text{g}$).

Geochemical Data for Water, Streambed Sediment, and Fish Tissue from the Sierra Nevada Mercury Impairment Project, 2011–12

By Elizabeth B. Stumpner, Charles N. Alpers, Mark Marvin-DiPasquale, Jennifer L. Agee, Evangelos Kakouras, Michelle R. Arias, Le H. Kieu, David A. Roth, Darrell G. Slotton, and Jacob A. Fleck

Abstract

This report presents geochemical data for surface water, streambed sediment, and fish tissue samples collected during low-flow conditions in 20 to 24 Sierra Nevada streams during 2011 and 2012. The dataset is part of a larger study designed to assess the factors that control mercury concentrations in fish tissue and to develop a model that predicts mercury concentration in the tissue of selected fish species in Sierra Nevada streams. The ranges of total mercury concentration observed in different matrices of water and sediment from 24 locations were as follows: below detection to 0.86 nanograms per liter in filtered water, below detection to 4.06 nanograms per liter in suspended particulates (greater than 0.3 micrometer in diameter), 1.1 to 381 nanograms per gram in bed sediment less than 2 millimeters, and 28.1 to 1,410 nanograms per gram in bed sediment less than 0.063 millimeters. The ratio of monomethyl mercury to total mercury ranged as follows: below detection to 19.2 percent in filtered water, below detection to 51.7 percent in suspended particles (greater than 0.3 micrometer), and below detection to 7.6 percent in streambed sediment less than 2 millimeters. Fish from 3 species collected at 20 locations had the following range in total mercury concentration (all concentrations wet weight): 10 to 292 nanograms per gram in rainbow trout (293 fish, 19 locations), 13 to 386 nanograms per gram in brown trout (33 fish, 10 locations), and 159 nanograms per gram in hardhead (1 fish). Concentrations of selenium in fish (wet weight) ranged from 60 to 420 nanograms per gram in rainbow trout (66 fish, 19 locations) and from 180 to 240 nanograms per gram in brown trout (6 fish, 2 locations).

Introduction

Historical hydraulic and hard-rock gold mining in California, starting with the Gold Rush in the late 1840s and continuing into the mid-1900s, left an estimated 4.5 million kilograms of mercury (Hg) in the environment (Churchill, 2000). The legacy effects of mining and stamp milling include Hg contamination of several rivers draining the western slope of the northern Sierra Nevada (Hunerlach and others, 2004; Alpers and others, 2005a) and downstream water bodies such as the Sacramento–San Joaquin Delta (Davis and others, 2008) and San Francisco Bay (Hornberger and others, 1999).

Mercury is a trace element found in the Earth's crust, atmosphere, and natural water. Monomethyl mercury, hereafter methylmercury or MeHg, is a neurotoxin that is biomagnified in the food web and threatens wildlife and human health (Fitzgerald and others, 1998; U.S. Environmental Protection Agency, 2001). Water bodies are considered impaired by the State of California under the federal Clean Water Act (CWA) if concentrations of total Hg (THg) in unfiltered water exceed 50 nanograms per liter (ng/L; California Toxics Rule; U.S. Environmental Protection Agency, 2000) or if concentrations of MeHg in fish tissue exceed 0.3 microgram per gram ($\mu\text{g}/\text{g}$; wet weight), equivalent to 300 nanograms per gram (ng/g; U.S. Environmental Protection Agency, 2001). The California State Water Resources Control Board (SWRCB) is responsible for enforcing the CWA in California. Section 303(d) of the CWA requires identification of water bodies with impaired beneficial uses. In response to SWRCB requests for assistance, the U.S. Geological Survey (USGS), in cooperation with the SWRCB, undertook the present study to collect environmental Hg data and analyze the factors that control Hg concentrations in fish tissue in the Sierra Nevada. Predictions of Hg concentrations in fish tissue for 185 stream segments in the Sierra Nevada were made by Alpers and others (2016), based in part on data contained in this report.

Purpose and Scope

This report documents the methods and results of field investigations during 2011 and 2012 in the Sierra Nevada foothills for the collection of water, sediment, and fish samples from 24 locations ([fig. 1](#)). The dataset is part of a larger study designed to assess the factors that control mercury concentrations in fish tissue and to develop a model that predicts mercury concentration in the tissue of selected fish species in Sierra Nevada streams. The main body of this report begins with the “[Introduction](#),” followed by sections “[Purpose and Scope](#)” and “[Study Design](#). [Following a brief description of the study design, the methods of sample collection and processing for water, sediment, and fish are introduced and followed by descriptions of analytical methods for all sample types. Quality-assurance and quality-control results are also presented in the “\[Methods\]\(#\)” section. Tables of data for water, sediment, and fish tissue samples are included and discussed briefly in the “\[Results\]\(#\)” section.](#)

Study Design

Sampling for this study took place in low-flow conditions during late summer and early autumn of 2011 and 2012. Water and sediment samples were collected from 24 sites, and fish were collected from 20 sites. Water and sediment samples were collected by USGS staff, and analyses were performed at USGS laboratories. Fish were collected by the University of California, Davis (UCD), with the exception of four sites where the California Department of Fish and Wildlife collected fish for the Surface Water Ambient Monitoring Program (SWAMP); information on SWAMP quality-assurance procedures are provided by Bonnema (2011). Fish analyses were completed by UCD staff and performed at a UCD laboratory. Three of the sites sampled in 2011 were resampled in 2012 to assess year-to-year variability. Sites were chosen based on location in the watershed and proximity to historical mining activities ([fig. 1](#)). Five field blanks and three field replicates were collected for water samples for quality assurance and quality control; three replicates were also collected for sediment samples. Site information for water, sediment, and fish collection is presented in [table 1](#). Site information for water and sediment replicates, and water blanks, is presented in [table 2](#).

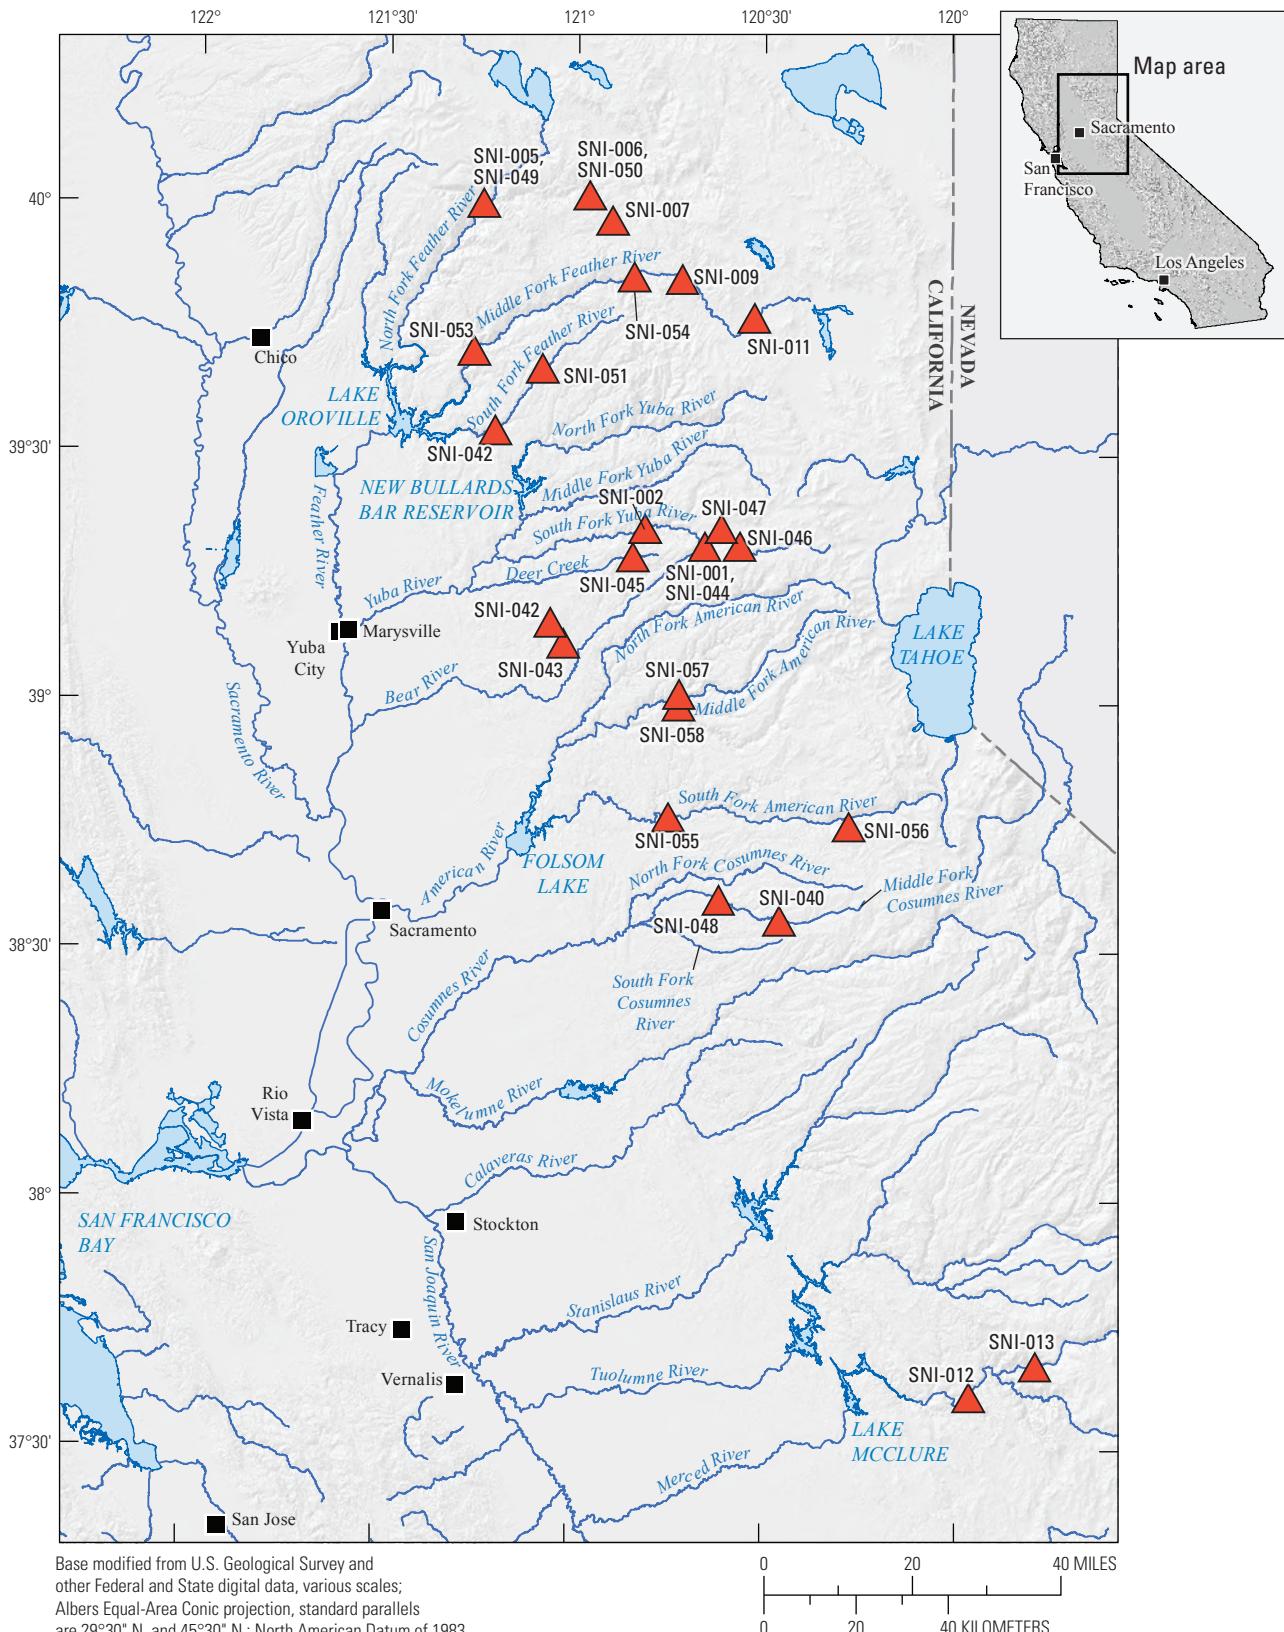

Figure 1. Location of Sierra Nevada Mercury Impairment Project sites for water, bed sediment, and fish. Discrete samples collected in 2011–12 across the Sierra Nevada foothills (red triangles).

Table 1. Location, date, and time of environmental water, sediment, and fish samples.

Methods

The following section includes the sample collection and processing methods, followed by a separate section describing analytical methods and quality assurance for surface water, bed sediment, and fish tissue.

Sample Collection and Processing Methods

Fish were collected on separate days from surface-water and bed-sediment samples to minimize disturbance at the site of field collection.

Surface Water

Water samples were collected in either Teflon containers or plastic containers lined with a fluoropolymer such as polytetrafluoroethylene (PTFE) and were processed using techniques described previously (Alpers and others, 2005b, 2008). Water was transferred to a Teflon-lined, stainless-steel churn within 24 hours of sample collection. Aliquots for THg, MeHg, dissolved organic carbon (DOC), and optical parameters related to carbon quality were filtered through pre-baked 0.3-micrometer (μm) glass-fiber filters (Advantec, Dublin, California). Aliquots for THg and MeHg were collected in polyethylene terephthalate glycol-modified (PETG) bottles (ThermoScientific, Waltham, Massachusetts), acidified to 0.5 percent by volume with ultrapure hydrochloric acid, and placed in the dark until analysis. One amber glass bottle was used to collect water for DOC and optical analyses. All other aliquots were filtered through 0.45- μm inline filters (Pall, Port Washington, New York) into high-density polyethylene (HDPE) containers. Aliquots for analysis of trace elements and cations (TE/Cations) were acidified to 0.1-percent concentration of ultrapure nitric acid.

Water-quality constituents measured in the field include temperature, pH, specific conductance, dissolved oxygen, and turbidity. All constituents were determined using a multiparameter YSI 6920 meter (YSI, Yellow Springs, Ohio) calibrated using procedures according to manufacturer recommendations and the USGS National Field Manual (Gibs and others, 2007).

Bed Sediment

Bed sediment was collected using an acid-rinsed polycarbonate core ring and a stiff acid-cleaned plastic sheet using techniques described previously (Marvin-DiPasquale and others, 2009). Sediment was sieved in the field to less than 2 millimeters (mm) and homogenized, then split into containers for analyses of Hg, dry weight, loss on ignition,

bulk density, porosity, iron species, and total reduced sulfur, and then placed on dry ice. Additional containers of less than 2-millimeter (mm) material were placed on wet ice for grain-size distribution analysis and for further sieving to less than 0.063-mm (63- μm) material in the laboratory for analysis of Hg and TE/Cations. Sediment sieving was done using stainless steel screens and deionized water. All water passing through a 0.063-mm sieve was retained, and the samples were dewatered using a centrifuge operated at 10,000 revolutions per minute.

Fish Tissue

Fish were collected by UCD with a backpack electroshocker and by angling to capture rainbow trout ($n = 237$), brown trout ($n = 33$), and hardhead ($n = 1$) from 20 sites. The fish were processed by the UCD laboratory as fresh (wet) samples. Fish sampling and preservation techniques were described previously by Saiki and others (2004).

Analytical Methods and Quality Assurance

Analytical methods used for water, sediment, and fish samples are listed in [appendix 1](#) as [tables 1–1](#), [1–2](#), and [1–3](#), respectively. For USGS-approved methods used by laboratories such as the USGS National Water Quality Laboratory (NWQL) in Denver, Colorado, the reader is referred to published sources for method information. This section provides more detailed information for research-based analytical methods that have recently been approved by the USGS, or that are not subject to formal approval.

Quality-assurance and quality-control (QAQC) results are presented in [appendices 2](#) (water), [3](#) (sediment), and [4](#) (fish). Where available, QAQC results are given for standard reference materials, laboratory duplicates, matrix spikes, equipment blanks, and field replicates. Results of QAQC for water analyses are given in [appendix tables 2–1](#) through [2–24](#), for sediment analyses in [appendix tables 3–1](#) through [3–15](#), and for fish analyses in [appendix tables 4–1](#) and [4–2](#). For ambient concentrations greater than three times the method detection limit (MDL), data-quality objectives of the project were met when the mean value of equipment blanks was below the MDL, the relative percent difference (RPD) among field replicates and laboratory duplicates was less than 20 percent for water analytes, the percent deviation (%DEV) between field replicates and laboratory duplicates was less than 20 percent for suspended and bed sediment analytes, and standard reference material (SRM) and matrix-spike recoveries were within a threshold of ± 20 percent of expected concentrations. Values of RPD were computed using [equation 1](#):

$$RPD \text{ (in percent)} = \frac{(v1 - v2)}{\left[\frac{v1 + v2}{2} \right]} \times 100 \quad (1)$$

where

$v1$ and $v2$ are values being compared.

For ambient concentrations less than three times the MDL, greater variability for replicates is expected, with values of RPD up to 100 percent at the MDL, including [equations 2](#) and [3](#). Unless specified otherwise, data-quality objectives of this project were met for all analytes.

The deviation (DEV, half of absolute relative difference) was calculated using equation 2:

$$DEV = \text{absolute } \frac{\text{run 1} - \text{run 2}}{2} \quad (2)$$

The percent deviation (%DEV) was then calculated using equation 3:

$$\%DEV = [DEV / mean] \times 100 \quad (3)$$

and is the percentage of DEV relative to the mean value.

Water

Surface water was analyzed for total mercury, methylmercury, total suspended solids, organic carbon and nitrogen, absorbance and fluorescence spectral indicators, total particulate carbon and nitrogen, nutrients, alkalinity, chlorophyll *a* and pheophytin-*a*, anions, suspended sediment concentration, and cations and trace elements.

Total Mercury

Total mercury (THg) in water samples was determined for filtered and particulate fractions at the USGS National Research Program, Western Branch (USGS-NRP-WB) Biogeochemistry Laboratory in Menlo Park, Calif. Cold vapor atomic fluorescence spectrometry (CVAFS) methods using a modified version of U.S. Environmental Protection Agency (EPA) Method 1631 (U.S. Environmental Protection Agency, 2002a, b) were previously described by Olund and others (2004). The MDL for THg in water samples analyzed in 2011 using the Tekran Model 2600 is 0.04 ng/L; for water samples analyzed in 2012, the MDL is 0.06 ng/L. For particulate samples (on filters), the MDL for THg is 0.03 nanogram per filter, corresponding to a volumetric concentration of approximately 0.07 ng/L, depending on volume filtered and the mass of sediment deposited on the filter.

Quality-assurance data for surface-water total mercury (filtered; THg-f) are presented in [appendix table 2–1](#).

Calibration standards were prepared from a National Institute of Standards and Technology (NIST)-certified, commercially obtained mercuric chloride ($HgCl_2$) standard. Three of the five equipment blanks were below the MDL, and the other two were 0.09 (estimated) and 0.10 ng/L ([appendix table 2–1B](#)).

Environmental sample concentrations ranged from less than the MDL to 0.86 ng/L. Two of the three replicate sample pairs had estimated concentrations between the MDL and the lower calibration standard. The RPD for these two pairs were 11 and 30 percent. A third replicate pair, with concentrations farther from the MDL, had a RPD of 1.7 percent, well within the acceptable range ([appendix table 2–1C](#)). All quality-assurance data for THg-f met the data-quality objectives of this project ([appendix table 2–1](#)).

Quality-assurance data for surface-water total mercury (particulate; THg-p) are presented in [appendix table 2–2](#). All three of the replicate pairs for THg-p included estimates between the MDL and the lowest calibration standard. Values of RPD for one of the three replicate pairs was less than 10 percent, but one of the pairs, the one with the lowest concentrations, had an RPD value of 70 percent ([appendix table 2–2C](#)). All other quality-assurance data for THg-p met the data-quality objectives of this project ([appendix table 2–2](#)).

Methylmercury

Monomethyl mercury (MeHg) in water samples was determined for filtered and particulate fractions by the USGS-NRP-WB Biogeochemistry Laboratory. The MeHg extraction and quantification was completed using a method developed by the Florida Department of Environmental Protection (2011, 2013). The potassium hydroxide/methanol extraction and CVAFS methods have been previously described by Marvin-DiPasquale and others (2011). The MDL for this method for filtered water is 4 picogram per liter (pg/L; or 0.004 ng/L). For particulate samples (on filters), the MDL for MeHg is 0.12 picogram per gram (pg/g), corresponding to approximately 8.2 pg per filter, or a volumetric concentration of approximately 0.004 ng/L, depending on volume filtered and the mass of sediment deposited on the filter. Two analytical runs were completed for all water samples. Calibration standards were prepared from a NIST-certified, commercially obtained MeHg standard. Quality-assurance data for filtered monomethyl mercury (MeHg-f) are presented in [appendix table 2–3](#). Quality-assurance data for MeHg-f met the data-quality objectives of this project with the exception of field replicate SNQ-054 ([appendix table 2–3C](#)), which had a 42-percent RPD from environmental sample SNI-054.

Quality-assurance data for particulate MeHg in water (MeHg-p) are presented in [appendix table 2–4](#). Quality-assurance data for MeHg-p met the data-quality objectives of this project with the exception of field replicates SNI-041 and SNQ-54, which had 25-percent RPDs from the environmental samples SNI-040 and SNI-54, respectively ([appendix table 2–4C](#)).

Total Suspended Solids

Total suspended solids (TSS) in water samples were determined by the USGS-NRP-WB Biogeochemistry Laboratory using the same 0.3- μm pore-diameter glass-fiber filters that were used to determine THg-p and MeHg-p concentrations. Twenty-seven laboratory duplicates of TSS measurements ([appendix table 2–5](#)) had a mean DEV and standard deviation of 0.09 ± 0.18 milligram per liter (mg/L). Values of %DEV for 18 of the 27 duplicate pairs for TSS analysis were less than 20%. Eight of the nine duplicate pairs with %DEV values above 20% had average TSS values less than 0.7 mg/L.

Organic Carbon

Dissolved organic carbon (DOC) was determined using high-temperature combustion and infrared detection on a total organic carbon analyzer (Model TOC-VCPh, Shimadzu Scientific Instruments, Columbia, Maryland) at the USGS Organic Matter Research Laboratory (OMRL) in Sacramento, Calif. (Stumpner and others, 2015). [Appendix table 2–6](#) presents quality-assurance data for matrix blanks, matrix spikes, and SRMs for DOC analyses. The MDL for DOC was 0.03 mg/L, and the laboratory reporting limit (LRL) was 0.3 mg/L. Quality-assurance data for DOC met the data-quality objectives of this project.

Absorbance and Fluorescence Spectral Indicators

Absorbance spectra were determined on a CARY-300 spectrophotometer (Agilent Technologies, Santa Clara, Calif.), and fluorescence matrices were determined on a Fluoromax-4 spectrofluorometer (Horiba Instruments, Edison, New Jersey) at the OMRL, previously described in Fleck and others (2014). The spectral correction procedures and measurements were within quality-assurance (QA) thresholds according to the daily water Raman peak area and laboratory reference material (Lipton, Unsweetened Black Tea, Purchase, N.Y.), as defined in Fleck and others (2014). [Appendix tables 2–7](#) and [2–8](#) present QA data for SRM data, equipment blanks, and field replicates. The SRMs in [appendix tables 2–7](#) and [2–8](#) are reported for absorbance and fluorescence, respectively; for absorbance wavelengths and fluorescence excitation-emission pairs, two SRMs were analyzed for each run date, and MDLs are reported for each absorbance wavelength and fluorescence excitation-emission pair. The daily detection limits (DDLs) associated with each absorbance sample are the five organic-free water blanks analyzed for that run date and calculated for each as three times the standard deviation (SD) plus the average. The DDLs associated with each fluorescence excitation-emission pair are based on one organic-free water blank. In cases where absorbance and fluorescence spectral indicators are ‘estimated’ values, relative percent difference was not calculated.

Total Particulate Carbon and Nitrogen

Analyses of total particulate carbon and nitrogen (TPCN) were done at the USGS NWQL in Denver, Colo., according to EPA Method 440 (Zimmermann and others, 1997). Constituents included particulate inorganic carbon (PIC), particulate organic carbon (POC), total organic carbon (TOC), and total particulate nitrogen (TPN). Collectively, this group of constituents is referred to as total particulate carbon and nitrogen (TPCN). Quality-assurance data for these constituents ([appendix table 2–9](#)) met the data-quality objectives of the project, with the exception of a replicate pair for TPN that had an RPD value greater than 20 percent.

Nutrients

Several forms of nitrogen and phosphorus were analyzed in surface-water samples at the USGS NWQL. Methods are listed in [appendix table 1–1](#). Organic nitrogen and ammonia were analyzed in unfiltered and filtered water. The following other nitrogen species were analyzed in filtered water only: nitrate plus nitrite, nitrite, and ammonia. Total phosphorus was analyzed in unfiltered and filtered water. Orthophosphate was analyzed in filtered water only. Quality-assurance data for nutrient analyses are provided in [appendix 2](#), as follows: unfiltered organic nitrogen plus ammonia ([appendix table 2–10](#)), filtered organic nitrogen plus ammonia ([appendix table 2–11](#)), filtered nitrate plus nitrite ([appendix table 2–12](#)), filtered ammonia ([appendix table 2–13](#)), filtered nitrite ([appendix table 2–14](#)), unfiltered total phosphorus ([appendix table 2–15](#)), filtered total phosphorus ([appendix table 2–16](#)), and orthophosphate ([appendix table 2–17](#)). Replicate RPD values for all nutrient constituents were less than 10 percent ([appendix tables 2–10 to 2–17](#)). Data for blanks and replicates for each of these constituents met the data-quality objectives of the project.

Alkalinity

Alkalinity of surface-water samples was determined by titration with sulfuric acid at the USGS NWQL. Quality-assurance data ([appendix table 2–18](#)) indicate low replicate RPD values (less than 1 percent). Alkalinity concentrations in equipment blanks were in the range of 2.7 to 4.6 mg/L as CaCO₃; the lowest alkalinity concentration for an environmental sample was 10 mg/L as CaCO₃. Therefore, the quality-assurance data for alkalinity met the data-quality objectives of the project.

Chlorophyll *a* and Pheophytin *a*

Chlorophyll *a* and pheophytin *a* were analyzed by fluorescence at the USGS NWQL. Quality-assurance data for chlorophyll *a* and pheophytin *a* are presented in [appendix table 2–19](#). No blank filters were submitted to the NWQL for analysis. The RPD values for two replicates were less than 10 percent for both constituents, which met the data-quality objectives of the project.

Anions

Concentrations of sulfate and chloride were determined by ion chromatography at the USGS NWQL. Methods are listed in [appendix table 1–1](#). Quality-assurance data are presented in [appendix tables 2–20](#) (sulfate) and [2–21](#) (chloride). Concentrations in equipment blanks were at or near the MDL for both constituents, well below the observed levels in all environmental samples. The RPD values for three replicates were less than 15 percent for both constituents, meeting the data-quality objectives for the project.

Suspended Sediment Concentration

Suspended sediment concentration (SSC) and percent fines (less than 0.063 mm) were analyzed at the USGS Santa Cruz Sediment Laboratory. Quality-assurance data for SSC ([appendix table 2–22](#)) indicate poor results for replicates; two of the three replicates had RPD values of 67 percent. However, for both of these replicate pairs, the observed concentrations were 1 and 2 mg/L, close to the MDL (0.5 mg/L). Three equipment blanks were analyzed for SSC. Two blanks had SSC results less than the MDL, and the third was 1.0 mg/L. Environmental samples had low SSC because sampling was done at low-flow conditions; 20 of 27 analyses were 2 mg/L or less, and only 1 of 27 analyses was greater than 5 mg/L. Therefore, the low range of reported SSC values for environmental samples (2 mg/L and less) should be used with caution, as it likely contains a high uncertainty.

Cations and Trace Elements

Fifty-four cations and trace elements were analyzed in filtered water by inductively coupled plasma (ICP). Atomic emission spectroscopy (AES) methods were used for major elements and mass spectroscopy (MS) methods for minor and trace elements. The ICP analyses were performed at the USGS National Research Program, Central Branch (USGS-NRP-CB) laboratory in Boulder, Colo. The methods were previously described by Marvin-DiPasquale and others (2009). Quality-assurance data for ICP analyses in water, including MDLs, equipment blanks, replicates, SRMs, and matrix-spike recoveries, are given in [appendix table 2–23](#). [Appendix tables 2–23A–E](#) report QAQC data for samples collected during 2011, and [appendix tables 2–24A–E](#) report QAQC data for samples collected during 2012. The USGS-NRP-CB laboratory reports the mean concentration of triplicate analysis. When two or three samples were collected for analysis, the NWIS environmental database stores the mean concentration data of the first bottle, and the NWIS QAQC database contains mean concentration data of the second bottle and when applicable, the third bottle.

Analytical results for the first equipment blank of the 2012 sampling season (SNQ-001) indicated high concentrations of several cations and trace elements. The high

values observed could be the result of contamination of the deionized water used for the blank or inappropriate cleaning techniques of sampling equipment. As a result, data for SNQ-001 are not included in the QA tables ([appendix tables 2–1 to 2–4, 2–6 to 2–10, 2–24A–E](#)).

For the remaining five blanks (three from 2011 and two from 2012), the 80-percent upper confidence level for the 80th percentile concentration of the equipment blanks (80 UCL) was estimated for each analyte using the Excel® confidence function (Microsoft Office®, 2010). The function requires the standard deviation of the mean of the five blanks and sample size. When blank concentrations were reported less than the MDL, the MDL was assigned as the sample concentration. The mean value of the blanks and confidence function were combined to determine the 80 UCL. Any environmental samples with concentrations less than the 80 UCL value were assigned a value-qualifier code of “V” in the database and tables, indicating that caution should be used in their interpretation. The UCL was not determined for cesium (Cs), erbium (Er), rhenium (Re), or vanadium (V) because the standard deviation of the mean was zero for these elements.

Bed Sediment

Bed sediment was analyzed for total mercury, methylmercury, reactive mercury, iron species, total reduced sulfur, organic content by loss on ignition, bulk density, dry weight, porosity, sediment grain size, and cations and trace elements.

Total Mercury

Total mercury in bed-sediment samples (THg-s) for sediment less than 2 mm and less than 0.063 mm was determined by the USGS-NRP-WB Biogeochemistry Laboratory. Subsamples for THg-s were analyzed following the USGS-approved method (Olund, 2004). Once thawed, approximately 0.25 grams (wet weight) of sediment was digested in aqua regia (2 milliliters [mL] concentrated hydrochloric acid and 6 mL nitric acid) for 24 hours. Bromine monochloride (5 percent weight per volume) was then added to each sample, which was subsequently heated to 50 °C in an oven overnight. Samples were then transferred to a pre-combusted glass container and analyzed on an automated mercury analyzer (Tekran Model 2600) according to EPA Method 1631, Revision E (U.S. Environmental Protection Agency, 2002a, b). The 2012 analytical run for THg for sediment less than 2 mm had one SRM with a percent recovery greater than the data-quality objectives of the project; other quality-assurance data for THg in sediment, which met the data-quality objectives of the project, are given in [appendix table 3–1](#).

Methylmercury

The concentration of MeHg in sediment samples (MeHg-s) was determined by the USGS-NRP-WB Biogeochemistry Laboratory. Extraction and quantification of MeHg-s was completed using a method developed by the Florida Department of Environmental Protection (2011, 2013). The potassium hydroxide/methanol extraction and CVAFS methods were described by Marvin-DiPasquale and others (2011). Quality-assurance data for MeHg in sediment, given in [appendix table 3–2](#), met the data-quality objectives of the project.

Reactive Mercury

Reactive mercury (Hg(II)_{R}) in bed sediment ($\text{Hg(II)}_{\text{R-s}}$) was determined by the USGS-NRP-WB Biogeochemistry Laboratory. The reactive mercury assay was previously described by Marvin-DiPasquale and Cox (2007). During the 15-minute reaction and N_2 purge step, Hg(II)_{R} was reduced to elemental Hg(0), which was trapped on a gold-coated-sand trap per EPA Method 1631 (U.S. Environmental Protection Agency, 2002b). The Hg(0) was then thermally desorbed from the gold-coated-sand trap onto a second gold-coated-sand analytical trap, using argon as a carrier gas. The analyte was then thermally desorbed from the analytical trap and sent through a CVAFS detection system. The CVAFS detector (Brooks Rand Model III mercury analyzer) communicates to peak-integration software (Peak Simple, Chrom Tech, Inc., Apple Valley, Minnesota) to convert the analog signal output to an integrated peak-area value. Quality-assurance data for Hg(II)_{R} are given in [appendix table 3–3](#). Laboratory duplicates ranged from 0.005–1.47 ng/g DEV. Two of the %DEV values were greater than 20 percent.

Iron Species

Iron (Fe) speciation in sediment samples was determined by the USGS-NRP-WB Biogeochemistry Laboratory. Three Fe fractions were chemically extracted and assayed as described by Marvin-DiPasquale and others (2009): acid-extractable ferrous iron ($\text{Fe(II)}_{\text{AE}}$), crystalline ferric iron ($\text{Fe(III)}_{\text{c}}$), and amorphous ferric iron ($\text{Fe(III)}_{\text{a}}$). The MDL for all Fe analysis was 0.01 mg/mL. Spectrophotometry, after a weak acid extraction, was used for the $\text{Fe(II)}_{\text{AE}}$ and $\text{Fe(III)}_{\text{c}}$ methods, whereas $\text{Fe(III)}_{\text{a}}$ required an additional reduction and spectrophotometric measurement. Quality-assurance data for $\text{Fe(II)}_{\text{AE}}$, $\text{Fe(III)}_{\text{c}}$, and $\text{Fe(III)}_{\text{a}}$, presented in [appendix tables 3–4 to 3–6](#), respectively, met the data-quality objectives of the project.

Total Reduced Sulfur

Total reduced sulfur (TRS) in sediment samples was determined by the USGS-NRP-WB Biogeochemistry Laboratory based on the heated acid/chromium distillation procedure by Fossing and Jørgensen (1989). The procedure was previously described by Marvin-DiPasquale and others

(2011). [Appendix table 3–7](#) presents quality-assurance data for TRS in sediment. All data met the data-quality objectives of the project with the exception of a %DEV value of 52 percent for a laboratory duplicate for a sample sieved to <2 mm, which is prone to more heterogeneity than the duplicate samples ($n = 4$) sieved to <0.063 mm.

Organic Content by Loss on Ignition

Loss on ignition (LOI), an indicator of organic content in sediment samples, was determined by the USGS-NRP-WB Biogeochemistry Laboratory in a method previously described by Marvin-DiPasquale and others (2009). [Appendix table 3–8](#) presents quality-assurance data for LOI in sediment. Values of DEV were less than 9 percent for all 18 replicate LOI analyses (12 sieved to less than 2 mm, 6 sieved to less than 0.063 mm), which met the data-quality objectives of the project.

Bulk Density, Dry Weight, and Porosity

Bulk density, dry weight, and porosity in sediment samples were determined by the USGS-NRP-WB Biogeochemistry Laboratory using methods previously described by Marvin-DiPasquale and others (2009). Quality-assurance data for dry weight, bulk density, and porosity are presented in [appendix tables 3–9 to 3–11](#), respectively. Values of DEV for laboratory replicates were less than 7 percent for each of these analytes, which met the data-quality objectives of the project.

Sediment Grain Size

Analyses of sediment grain-size distribution were performed at the USGS California Water Science Center (CAWSC) Hydrologic Research Laboratory. Bed-sediment material smaller than 2 mm was analyzed on a model LS 13 320 single-wavelength laser diffraction particle-size analyzer (LDPSA, Beckman-Coulter, Pasadena, Calif.). Prior to analysis, samples were dried at 55 °C and were split into representative aliquots using a Sieving Riffler (Quantachrome Instruments, Boynton Beach, Florida). Material that did not fit through a 1-mm sieve was excluded. Approximately 500 mg of sediment was placed in the LDPSA unit, which uses a 5 milliwatt laser diode with a wavelength of 750 nanometers. A dispersing agent was used to break up aggregated particles. The composite light-scattering pattern was measured by 126 detectors placed at angles up to approximately 35 degrees from the optical axis (Beckman Coulter, Inc., 2011). In the LDPSA, the composite scattering pattern was deconvolved to a set of individual numbers, one for each size classification, and the relative amplitude of each number is a measure of the relative volume of equivalent spherical particles of that size. This deconvolution is based on the Fraunhofer optical model, the instrument default, which assumes that the particle diameter is much larger than the wavelength of the light and that the refractive index of the particles is different than that of the transport medium, in this case, water (Beckman Coulter, Inc., 2011).

Each sample was run in duplicate, and the median grain-size (D50) values for the two runs were compared by RPD. If the RPD was greater than 10 percent, then additional aliquots were analyzed until a pair of analyses had D50 values that produced an RPD value of less than 10 percent. A total of 31 laboratory duplicates were analyzed (28 environmental samples and 3 field replicates), with a mean RPD for D50 (median grain size) of 3.8 ± 2.9 percent ([appendix table 3–12](#)). Of the 31 samples analyzed for grain-size distribution, 8 (or 27 percent) required analysis of more than two aliquots.

Raw data from the LDPSA were post-processed using MATLAB (The MathWorks, Inc., Natick, Mass.) to produce tabular data in 1/2-phi size bins and to compute the proportions of sand, silt, and clay in each sample ([appendix table 3–13](#)). The phi scale for sediment particles is defined in equation 4:

$$\text{phi} = -\log(\text{base } 2) (\text{diameter in mm}) \quad (4)$$

such that a phi of 0 corresponds to 1 mm, a phi of 2 corresponds to 0.25 mm (1/4 mm), a phi of 4 is 0.0625 mm (1/16 mm), and a phi of 8 is approximately 0.004 mm (1/256 mm; Poppe and others, 2003).

Trace Elements and Major Elements

Fifty-four major and trace elements were analyzed in bed sediment less than 0.063 mm by ICP-AES (major elements) and ICP-MS (trace elements) at the USGS-NRP-CB laboratory in Boulder, Colo., according to methods previously described by Alpers and others (2005b). Quality-assurance data for ICP analyses in bed sediment, including data on SRMs and matrix-spiked recovery and digest replicate data, are presented in [appendix tables 3–14](#) and [3–15](#). [Appendix tables 3–14A–E](#) report QAQC data for samples collected during 2011, and [appendix tables 3–15A–E](#) report QAQC data for samples collected during 2012.

The USGS-NRP-CB laboratory digests sediment samples in duplicate and completes analysis in triplicate. Here we report the mean concentration of triplicate analysis. When two mean concentrations were reported, the NWIS environmental database stores the mean concentration data of the first digestion, and the NWIS QAQC database contains the mean concentration data of the second digestion. The RPD values reported in [appendix tables 3–14](#) through [3–15](#) for digestion replicates compare the average concentrations determined for each of the two digestions.

Fish Tissue

Fish were analyzed for mercury and selenium. Analytical methods and QAQC results for these analytes are described below.

Mercury

Fish for analysis were thawed, weighed, and measured. Individuals within the human-health-relevant size ranges (greater than or equal to approximately 150 mm) were analyzed for fresh weight muscle mercury. Muscle samples were dissected subcutaneously from the dorsolateral (shoulder) region and weighed directly into digestion tubes.

Sample mercury was reduced to the molecular level in solution through digestion at 90 °C in a mixture of concentrated nitric and sulfuric acids, followed by a second stage of heated digestion with the addition of oxidizing potassium permanganate. Fully digested samples were analyzed for total mercury by standard cold vapor atomic absorption (CVAA) spectrophotometry, using a dedicated Perkin-Elmer Flow Injection Mercury System (FIMS) with an AS-90 autosampler. Quality assurance and quality control were employed throughout the analytical process as QAQC samples passed through the same digestion process and chemical addition as field samples. Routine QAQC included, for each batch of 20–60 samples, 8 aqueous mercury standards spanning the relevant range of concentrations. For each 20 analytical samples, the following QAQC samples were analyzed: 3 method blanks, 3 certified reference materials, 3 continuing calibration samples, 1 aqueous mercury laboratory calibration standard, 1 sample duplicate (another muscle sample dissected from the same fish), 1 sample duplicate spiked with mercury, and 1 spike duplicate. Results for THg from 27 analyses of two certified reference tissues—National Research Council of Canada (NRCC) DOLT-4 CRM dogfish liver, 2,580 ng/g mean dry weight, and NRCC DORM-3 CRM dogfish muscle, 382 ng/g mean dry weight—were within certified or recommended means, and ranges had a mean recovery of 99.3 percent with a standard deviation (SD) of 2.7 percent. Additionally, 54 within-run calibration samples were tested by repeatedly analyzing tissue-based samples and had a mean recovery of 98.5 percent with an SD of 1.8 percent. Eighteen laboratory calibration standards had a mean recovery of 105.6 percent with an SD of 1.8 percent. Recovery of mercury from 18 duplicate tissues spiked prior to digestion had a mean recovery of 98.0 percent with an SD of 1.3 percent. Method precision, determined by analyzing 18 duplicate pairs of fish tissue samples, varied from 0.1 to 6.9 RPD.

Recovery of mercury from 18 tissues spiked prior to digestion was 99.3 percent with an SD of 1.9 percent. Overall, these quality-control results were well within acceptable limits as specified by the UCD laboratory. Results from the fish mercury QAQC are presented in [appendix table 4–1](#).

Selenium

Fish tissue was analyzed for selenium (Se) at the USGS-NRP-WB Biogeochemistry Laboratory using hydride generation isotope dilution inductively coupled plasma mass spectrometry (HG-ID-ICP-MS) methods. Selenium analysis was completed on a subset of fish tissue from fish that had also been analyzed for Hg. An amendment with ^{82}Se enriched isotope in the form of Se^{6+} was used for the isotope dilution (U.S. Environmental Protection Agency, 2007). This method involved a multi-step wet digestion with a mixture of nitric acid (HNO_3) and hydrogen peroxide (H_2O_2 ; Elrick and Horowitz, 1985; Liber, 2012) and incubation with a pressure-steam sterilizer for 3 hours at 20 pounds per square inch and 125 °C. Digestates were subsequently reacted with concentrated hydrochloric acid (HCl) to reduce selenium to the most favorable Se^{4+} valence for hydride generation (Presser and Barnes, 1984). The solutions were then analyzed on a Perkin-Elmer (Elan DRC II) ICP-MS equipped with a flow injection system (FIAS-400). Polyatomic, isobaric, and background interferences were removed through the use of hydride generation and ^{82}Se enriched isotope spike. Quality-assurance data for Se in fish tissue are presented in [appendix table 4–2](#). The median Se concentration ($n = 6$) of the matrix blanks was 0.008 µg/g. Recovery of the standard reference materials, NIST2976 and DORM-2, ranged from 94.8 to 104.4 percent, well within the data-quality objectives of the study.

Results

The following section includes text and data tables describing surface water, bed sediment, and fish tissue results.

Water

Data for field measurements, laboratory alkalinity, and suspended sediment concentration are presented in [table 3](#). Data for THg, MeHg, and TSS are presented in [table 4](#). Concentrations of dissolved and particulate organic matter, particulate inorganic carbon, and total particulate nitrogen are presented in [table 5](#). Data for absorbance spectral indicators of dissolved organic matter composition are presented in [table 6](#); data for fluorescence spectral indicators are in [table 7](#). Concentrations of nitrogen species are presented in [table 8](#). Concentrations and phosphorus species and concentrations of selected anions are presented in [table 9](#). Concentrations of selected cations and trace elements from filtered water samples are presented in [tables 10A–E](#).

Concentrations of THg-f ranged from 0.04 to 0.86 ng/L ([table 4](#)). For THg-p, concentrations ranged from less than the MDL to 4.06 ng/L ([table 4](#)). Concentrations of MeHg-f ranged from less than the MDL to 0.044 ng/L ([table 4](#)). For MeHg-p, concentrations ranged from less than the MDL to 0.053 ng/L ([table 4](#)). The ratios of MeHg-f to THg-f (%MeHg-f) ranged

from less than the MDL to 19.2 percent ([table 4](#)). In suspended particulates, the ratios of MeHg-p to THg-p (%MeHg-p) ranged from less than the MDL to 51.7 percent ([table 4](#)).

Bed Sediment

Data for THg, MeHg, Fe species, and TRS in the less than 2-mm size fraction of sediment are presented in [table 11](#), together with dry weight, LOI, and bulk density data; similar data for the less than 0.063-mm size class of sediment are presented in [table 12](#). Summary statistics of laser diffraction analysis for sediment sizes less than 2 mm, including percent clay, silt, and sand, and mean and median grain size, are presented in [table 13](#). Detailed grain-size distribution data (in 1/2-phi intervals) obtained through laser diffraction analysis are available in [appendix table 3–13](#). For this report, percent clay was calculated as percentage (by weight) of bed-sediment material smaller than 0.004 millimeters, percent silt was calculated as percentage (by weight) of bed-sediment material smaller than 0.0625 mm but larger than 0.0004 mm, and percent sand was calculated as percentage (by weight) of bed-sediment material smaller than 2 mm but larger than 0.0625 mm. Summary statistics included in [table 13](#) were reported by the analytical instrument software but can be calculated using equations from Bunte and Abt (2001). Data for major elements and trace elements in the less than 0.063-mm sediment size class are presented in [table 14](#).

The results of the laser-scattering method (with dispersing agent) indicated a median sand content of 90.1 percent with a range from 64.1 to 96.9 percent ([table 13](#)).

Concentrations of THg in bed sediment from 24 sites ranged from 1.1 to 381 ng/g (dry weight) in material less than 2 mm and from 28.1 to 1,410 ng/g (dry weight) in material less than 0.063 mm. The ratios of MeHg-s to THg-s (percent MeHg-s) ranged from 0.04 to 7.6 percent in the less than 2-mm streambed sediment.

Fish Tissue

A summary of fish tissue THg concentration data by site and species is presented in [table 15](#). Data for THg concentration, total length, and weight of individual fish are given in [table 16](#). Data for Se in fish tissue are given in [table 17](#).

Fish from three species collected at 20 locations had the following range in total mercury concentrations (all concentrations wet weight): 10 to 292 ng/g in rainbow trout (*Oncorhynchus mykiss*; $n = 293$, 19 locations); 13 to 386 ng/g in brown trout (*Salmo trutta*; $n = 33$, 10 locations); and 159 ng/g in hardhead (*Mylopharodon conocephalus*; $n = 1$). Concentrations of selenium in fish (dry weight) ranged from 280 to 1,940 µg/g in rainbow trout ($n = 66$, 19 locations), and from 870 to 1,140 µg/g in brown trout ($n = 6$, 2 locations). The concentrations of selenium in fish converted to wet weight using average water content for axial fillet muscle tissue for each species (78.21 percent for rainbow trout and 77.48 percent for brown trout) ranged from 60 to 420 ng/g in rainbow trout and from 200 to 260 ng/g in brown trout.

Table 3–13. Data for grain-size distribution in sediment determined by laser diffraction; phi classification.

[All analyses completed at the U.S. Geological Survey California Water Science Center. The phi (ϕ) scale for sediment particles is defined as $\phi = -\log(\text{base } 2) (d \text{ in millimeter [mm]})$ such that a phi of 0 corresponds to 1 mm, a phi of 2 corresponds to 0.25 mm (1/4 mm), phi of 4 is 0.0625 mm (1/16 mm), and phi of 8 is approximately 0.004 mm (1/256 mm). Values in phi columns indicate percentage of sediment sample (by volume) in 1/2-phi size bin smaller than indicated phi size]
