

Amendments to the Report on
Development of a Highway Driving Cycle
for Fuel Economy Measurements

Introduction:

This report addresses several changes which have been made to the highway driving cycle described in the report entitled, "Development of a Highway Driving Cycle for Fuel Economy Measurements," dated March, 1974.

Purpose:

The purpose of this report is to explain the reasons for modifying the driving cycle and to summarize the characteristics of the updated tabulation of the cycle.

Objective:

The objective of this report is to produce an amended speed versus time tabulation of the highway driving cycle that is compatible with all chassis dynamometers.

Background:

The initial tabulation of the highway driving cycle was derived in a three step process. The speeds were read from the actual trace at .1 inch intervals, each interval representing 1.5 seconds. This file was recomputed by a linear interpolation to yield a file with speeds for each .5 second interval. By deleting every other point from this .5 second file, a tabulation of speed versus time was constructed at 1.0 second intervals.

The characteristics of the various segments of the cycle were computed from the "1.5" second file and were published as Table 3 in the March, 1974 report on cycle development.

Several organizations that have used the highway driving cycle (1.0 second tabulation) reported that the initial acceleration and final deceleration rates were high enough to cause belt slippage on dynamometers with belt-driven inertia weights. Calculations show that the rates were about 4.9 mph/sec.

The MSAPC laboratory has had no problems driving the cycle on the direct-drive dynamometers. However, our experience with the development of the LA-4 on belt-driven dynamometers supports the problem cited above. The accelerations and decelerations on the LA-4 were normalized to 3.3 mph/sec or less to avoid the slippage and wear problems.

This precedent has been applied to the highway driving cycle to permit the use of this cycle on all existing equipment without causing abnormal slippage and wear.

It was also reported that a summation of the (1.0 second) speed versus time list did not agree exactly with the values shown in Table 3. Although the differences were very small, this report will summarize the characteristics for the updated speed-time tabulation.

Discussion of Amendments:

It was agreed among the engineers involved in the cycle development that changes should be made only to the segments that were above the 3.3 mph/sec limit rather than a simple linearization to 0 mph at each end of the trace. Table A shows the tabulations of the two versions to illustrate which speeds were changed. Two seconds were added to the acceleration and a one second shift was made on the deceleration profile.

After these changes were made, a summation of the entire file was computed for each segment and for the total cycle. This exercise revealed the reason for the disparity between Table 3 and the summary of the tabulated speeds. The values in Table 3 were computed from the (1.5 second) file of speed versus time. In that file, two segments, C and B ended on half seconds; therefore, these points were not shown in the (1.0 second) tabulation.

This difference and the fact that the composite of Table 3 is simply a summation of the four segments produces a small variation in the final numbers.

Because the official version of the highway driving cycle will be the one second tabulation of speed versus time, the appropriate summary of characteristics should be based on this tabulation. This summary has been made. The values have been shown in parentheses with the previous values of Table 3 for comparison. Note that the average speed is now based on total sample time rather than total driving time. This value has no impact on the calculation of fuel economy.

The value of major impact on the calculation of fuel economy is the total distance traveled. The new value of 10.242 miles differs by + .16% from the previous value of 10.225. This updated value reflects the increase in time and the changes in speeds made to normalize the acceleration and deceleration rates.

Conclusions and Recommendations:

The changes which have been made to the highway driving cycle should permit its use without problems. The updated tabulation dated (Monday April 22, 1974) is recommended for adoption as the official driving cycle for highway fuel economy measurements.

The magnitude of the changes which have been incorporated into the updated version are not significant enough to invalidate any tests which have been performed using the previous version. It is recommended that previous measurements be accepted as valid and equivalent indications of highway fuel economy.
