ABSTRACT

A genetic analysis of samples from the Chinook salmon (*Oncorhynchus tshawytscha*) bycatch of the 2016 Bering Sea-Aleutian Island (BSAI) trawl fishery for walleye pollock (Gadus chalcogrammus) was undertaken to determine the overall stock composition of the bycatch. Samples were genotyped for 43 single nucleotide polymorphism (SNP) DNA markers and results were estimated using the Alaska Department of Fish and Game (ADF&G) SNP baseline. In 2016, genetic samples from the Bering Sea were collected using a systematic random sampling protocol where one out of every 10 Chinook salmon encountered was sampled. Based on the analysis of 1,910 Chinook salmon bycatch samples collected throughout the 2016 BSAI walleye pollock trawl fishery, Coastal Western Alaska and British Columbia regions (34% and 29% respectively) dominated the sample set with smaller contributions from West Coast US (14%), and North Alaska Peninsula (13%) regions. Analysis of temporal groupings within the pollock "A" and "B" seasons revealed changes in stock composition during the course of the year with lower contributions of Coastal Western Alaska and North Alaska Peninsula regions and higher contributions of West Coast US, British Columbia, and NW Gulf of Alaska, regions during the "B" season when compared to the "A" season.

INTRODUCTION

Pacific salmon (*Oncorhynchus* spp.) are prohibited species in the federally managed Bering Sea and Gulf of Alaska (GOA) groundfish fisheries, which are subject to complex management rules (NPMFC 2017a,b) that are in part designed to reduce prohibited species catch (PSC; hereafter referred to as "bycatch"). It is important to understand the stock composition of Pacific salmon caught in these fisheries, which take place in areas that are known feeding habitat for multiple brood years of Chinook salmon (Oncorhynchus tshawytscha) from many different localities in North America and Asia (Myers et al. 2007, Davis et al. 2009). Chinook salmon are economically valuable and highly prized in commercial, subsistence and sport fisheries. Determining the geographic origin of salmon caught in federally managed fisheries is essential to understanding the effects that fishing has on Chinook salmon stocks, especially those with conservation concerns (NPFMC 2012). This report provides genetic stock identification results for the Chinook salmon bycatch samples collected from the U.S. Bering Sea (BS) walleye pollock (Gadus chalcogrammus) trawl fishery. National Marine Fisheries Service (NMFS) geographical statistical areas (NMFS area) associated with the BS groundfish fishery (areas 509-524) and Alaska Department of Fish and Game (ADF&G) statistical areas (for details see http://www.adfg.alaska.gov/static/fishing/PDFs/commercial/chart03 bs.pdf) are shown in Figure 1 and are used later in the report to describe the spatial distribution of the Chinook salmon bycatch and genetic samples.

Amendment 91 to the North Pacific Fishery Management Council (NPFMC) Fishery Management Plan (FMP) for groundfish of the BSAI Management Area was enacted in 2010 and included retention of the all salmon caught in the pollock fishery. In 2011, a systematic random sampling design recommended by Pella and Geiger (2009) was implemented by the Alaska

Fisheries Science Center's (AFSC) Fisheries Management and Analysis (FMA) North Pacific Groundfish and Halibut Observer Program (Observer Program) to collect genetic samples from one out of every 10 Chinook salmon encountered as bycatch in the BS pollock fishery.

In 2016, genetic samples were collected by the Observer Program from the Chinook salmon bycatch of the BS pollock fishery by using the systematic sampling protocols recommended previously (Pella and Geiger 2009). The number of available samples and the unbiased sampling methodology facilitated the extrapolation of the sample stock composition to the overall Chinook bycatch from the BS pollock trawl fishery in 2016. Stock composition analyses were performed using the single nucleotide polymorphism (SNP) baseline provided by the ADF&G (Templin et al. 2011), the same baseline that was used previously to estimate stock composition of samples from the 2005-2015 Chinook salmon bycatch (NMFS 2009; Guyon et al. 2010a, b; Guthrie et al. 2012-2017; Larson et al. 2013). For additional information regarding background and methodology, refer to the Chinook salmon bycatch report prepared previously for the 2008 Bering Sea trawl fishery (Guyon et al. 2010a).

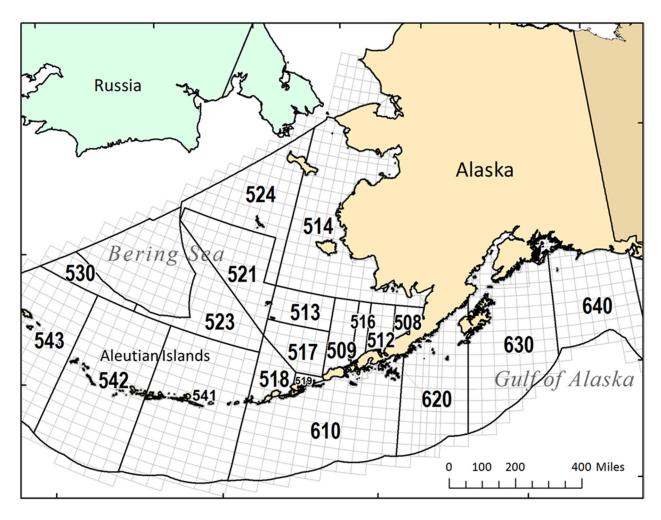

Figure 1. -- NMFS (outlined in black) and ADF&G (outlined in light gray) statistical areas associated with the Bering Sea and Gulf of Alaska groundfish fisheries.

SAMPLE DISTRIBUTION

Samples were collected from the Chinook salmon bycatch by the Observer Program for analysis at AFSC's Auke Bay Laboratories (ABL). Samples of axillary process tissue and scales were collected from the Chinook salmon bycatch throughout 2016. Axillary process tissues were stored in coin envelopes which were labeled, frozen, and shipped to ABL for analysis. Scales were collected as an additional source for genetic analysis, and for ageing if funding is available.

In 2016, an estimated 21,926 Chinook salmon were taken in the bycatch of BSAI pollock trawl fisheries (NMFS 2017). The Chinook salmon bycatch estimate is 38% below the historical

average (35,309) for the Bering Sea between 1991 and 2015 (Fig. 2) (Table 1). Since 1991, and far below the highest overall Chinook bycatch in 2007 (Fig. 2) when an estimated 121,770 fish were taken. Of the total 2016 bycatch, 16,828 were from the trawl "A" season (01/01/16 to 6/10/16) and 5,098 were from the "B" season (6/11/16 to 12/31/16).

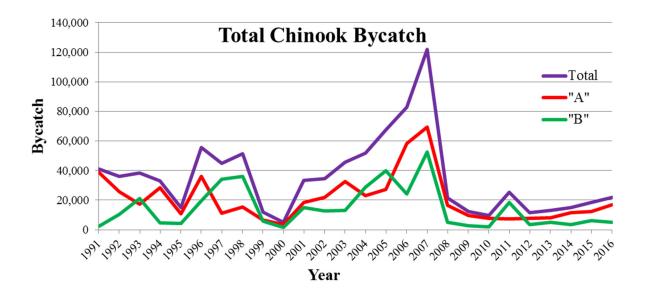

Figure 2. -- Yearly, "A" and "B" season estimates for the Chinook salmon bycatch from the Bering Sea pollock trawl fishery (NMFS 2017).

In 2016, there were 2,148 genetic samples received from the BS Chinook salmon bycatch collected by the observer program; of those 1,910 were successfully genotyped for an overall genotyped sampling rate of 8.7% ("A" season had 1,488 fish, 8.8% sampling rate; "B" season had 422 fish, 8.3% sampling rate).

Table 1. -- Annual, "A" and "B" season estimates for the Chinook salmon bycatch from the Bering Sea-Aleutian Island pollock trawl fishery (NMFS 2017).

| Year | Total | "A" Season | "B" Season |
|------|---------|------------|------------|
| 1991 | 40,906 | 38,791 | 2,114 |
| 1992 | 35,950 | 25,691 | 10,259 |
| 1993 | 38,516 | 17,264 | 21,252 |

| 2006 | 82,695 | 58,391 | 24,304 |
| 2007 | 121,770 | 69,420 | 52,350 |
| 2008 | 21,480 | 16,638 | 4,842 |
| 2009 | 12,369 | 9,711 | 2,658 |
| 2010 | 9,697 | 7,630 | 2,067 |
| 2011 | 25,499 | 7,137 | 18,362 |
| 2012 | 11,344 | 7,765 | 3,579 |
| 2013 | 13,034 | 8,237 | 4,797 |
| 2014 | 15,031 | 11,539 | 3,492 |
| 2015 | 18,329 | 12,304 | 6,025 |
| 2016 | 21,926 | 16,828 | 5,098 |

Potential biases primarily introduced through spatial and temporal aspects of genetic sample collection from the bycatch are well documented and have the potential to affect resulting stock composition estimates (Pella and Geiger 2009). The distributions of 2016 Chinook salmon bycatch genetic samples were evaluated by comparing the collection of genetic samples with the overall bycatch distribution (Figs. 3 and 4). The temporal distribution of samples collected and successfully genotyped was evaluated across the two fishing seasons (Fig. 3). The sample spatial distribution was compared with the total bycatch by NMFS statistical area (NMFS area) over

time (Fig. 4). 2016 was the sixth year that systematic random sampling was employed for collecting genetic tissue from the Bering Sea Chinook salmon bycatch and Figure 4 shows the resulting genetic samples were spatially and temporally representative of the total Chinook bycatch (i.e., those fish not sampled for bycatch).. As in 2011-2015, the sample spatial and temporal distribution were well aligned in 2016 compared to previous years when samples were collected more opportunistically (Guyon et al. 2010a,b; Guthrie et al. 2012-2017).

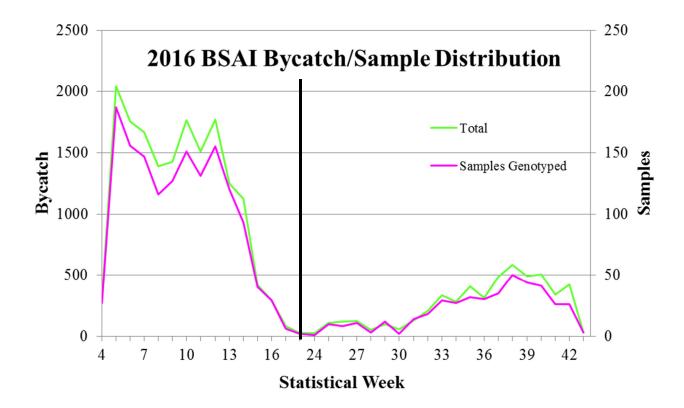

Figure 3. -- Number of Chinook salmon bycatch and genetic samples successfully genotyped graphed by statistical week. Weeks 4-18 correspond to the groundfish "A" season, whereas weeks 24-43 correspond to the "B" season, the demarcation of which is a vertical line.

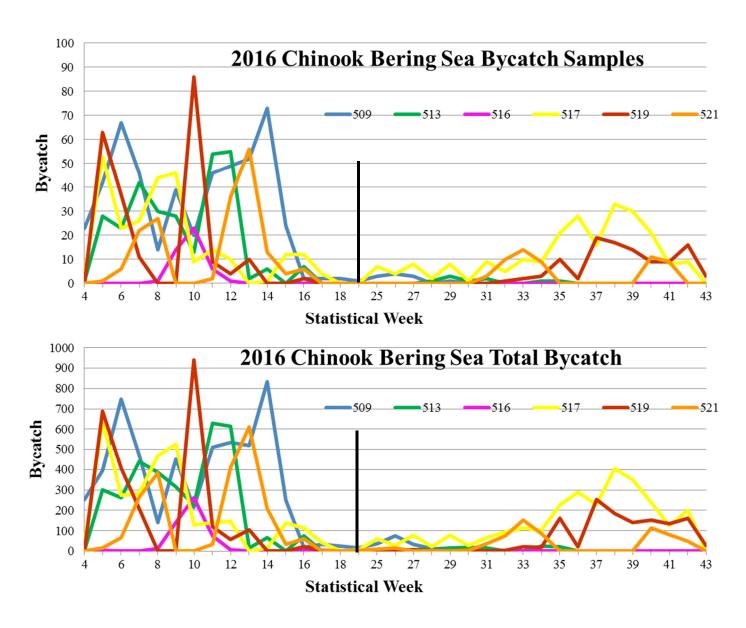

Figure 4. -- Comparison of the Chinook salmon bycatch by time and area with the distribution of available genetic samples. Top panel: Distribution of the 1,910 successfully genotyped samples from the 2016 bycatch. Not graphed were 11 fish from NMFS area 523. Bottom panel: Distribution of the Chinook salmon caught in the 2016 Bering Sea pollock trawl fishery. Not graphed were 136 fish each from NMFS area 523, and 5 fish from NMFS area 524. Weeks 4-18 correspond to the groundfish "A" season, whereas weeks 24-43 correspond to the "B" season, the demarcation of which is a vertical line.

LABORATORY ANALYSIS

DNA was extracted from axillary process tissue and genotyping was performed by using TagmanTM chemistries Applied Biosystems Inc. on a Life Technologies QuantStudioTM or by matrix-assisted laser desorption/ionization - time of flight (MALDI-TOF) (Guyon et al. 2010a) on a Sequenom MassARRAY iPLEX platform (Gabriel et al. 2009) for the 43 SNP DNA markers represented in the Chinook salmon baseline (Templin et al. 2011). The SNP baseline contains genetic information for 172 populations of Chinook salmon grouped into 11 geographic regions (also known as stock groups or reporting groups) (Appendix 1). Proof tests performed previously have shown the baseline to be suitable for stock composition analysis (Templin et al. 2011). TagmanTM assays were compared to internal controls for both open array (OA) and 384well formats using the QuantStudioTM. The concordance rate between OA and 384 formats was 99.99%. In addition to internal MALDI-TOF chip controls, 10 (out of 384 on a chip) previously genotyped samples from ADF&G, which used TagManTM chemistries were included on each chip during the analyses and resulting genotypes were compared. Concordance rates of 99.9% between the two chemistries for the 2016 controls confirmed the utility and compatibility of both genotyping methods.

From the 2016 Chinook salmon bycatch from the Bering Sea pollock trawl fishery, a total of 2,148 samples were analyzed of which 1,910 samples were successfully genotyped for 35 or more of the 43 SNP loci, a success rate of 88.9%. The remaining 1,910 successfully genotyped samples had genetic information for an average of 42 of 43 markers. Stock composition estimates were derived from BAYES software (Bayesian analysis; Pella and Masuda 2001; Appendix 2). The BAYES results were compared to SPAM software, (maximum likelihood analysis; ADF&G 2003) and both methods yielded almost identical stock composition estimates,

so only the BAYES results are reported here. BAYES software uses a Bayesian algorithm to produce stock composition estimates and can account for missing alleles in the baseline (Pella and Masuda 2001). For each BAYES analysis, 11 Monte Carlo chains starting at disparate values of stock proportions were configured such that 95% of the stocks came from one designated region with weights equally distributed among the stocks of that region. The remaining 5% were equally distributed among remaining stocks from all other regions. For all estimates, a flat prior of 0.005814 (calculated as 1/172) was used for all 172 baseline populations. The analyses were completed for a chain length of 10,000 with the first 5,000 deleted during the burn-in phase when determining overall stock compositions. Convergence of the chains to posterior distributions of stock proportions was determined with Gelman and Rubin shrink statistics (Gelman and Rubin 1992), which were 1.02 or less for all the estimates, conveying strong convergence to a single posterior distribution (Pella and Masuda 2001).

STOCK COMPOSITION RESULTS

Results (BAYES) suggest that 60% of the 1,488 samples from the "A" season originated from Alaska river systems flowing into the Bering Sea (all regions north of the Aleutian Islands except for Russia) with the Coastal Western Alaska region contributing the most (39%), followed by the North Alaska Peninsula (17%), and Upper Yukon (2%). The other major contributors were British Columbia (26%), West Coast US (9%), and Coastal Southeast Alaska (4%) (Appendix 2). For the "B" season, over 81% of the 422 samples originated from regions south of the Aleutian chain with the British Columbia region contributing the most (37%), followed by the West Coast US (30%), Coastal Western Alaska 17%, Coastal Southeast Alaska (7%) and Northwest GOA (6%) regions, (Appendix 2).

For the entire year, 50% of the bycatch samples were estimated to be from Alaska river systems flowing into the Bering Sea with the Coastal Western Alaska region contributing the most (34%), trailed by the North Alaska Peninsula (13%), Upper Yukon (2%) and Middle Yukon (2%). Other contributors were British Columbia (29%), West Coast US (14%), Coastal Southeast Alaska (4%), and Northwest GOA (2%) (Appendix 2).

To investigate how stock compositions might vary among smaller areas, "A" season estimates were developed for five strata with sufficient numbers of samples as follows (Appendix 2, Figs. 1, 5-8): Saint George Island (335 samples, Fig. 6), Northwest Bering (554 samples, Fig. 7), Catcher Vessel Operation Area (CVOA) (715 samples, Fig. 8), Southeast Bering (934 samples, Fig. 7), and NMFS area 509 (501 samples, Fig. 1, 6) (NMFS 2017). It should be noted that some of these strata overlap. For the Saint George and Northwest Bering strata, the resulting stock compositions showed that 83% and 85% respectively were estimated to be from Alaska river systems flowing into the Bering Sea. The largest contributors were Coastal Western Alaska (51% for Saint George, 49% for Northwest Bering) and North Alaska Peninsula (23% for Saint George, 24% for Northwest Bering), followed by Upper Yukon (6% for Saint George and Northwest Bering). Fifteen percent of the samples from Saint George and 17% for Northwest Bering strata were from regions south of the Aleutians, where the largest contributors were British Columbia (8% for Saint George, 11% for Northwest Bering), and Coastal Southeast Alaska (4% for Saint George, 3% for Northwest Bering). For the Catcher Vessel Operational Area (CVOA), Southeast Bering, and NMFS area 509 strata, more than half of the resulting stock composition estimates were from regions south of the Aleutians. The largest contributors were British Columbia (36% for CVOA, 35% for Southeast Bering, 39% for NMFS area 509), West Coast US (14% for CVOA, 13% for Southeast Bering, 15% for NMFS area 509), and

Coastal Southeast Alaska (5% for CVOA, Southeast Bering and NMFS area 509). At least 40% of CVOA (42%), Southeast Bering strata (46%), and NMFS area 509 (40%) were estimated to be from Alaskan river systems flowing into the Bering Sea. The largest contributors were Coastal Western Alaska (34% for CVOA, 34% for Southeast Bering, and 22% for NMFS area 509), and North Alaska Peninsula (8% for CVOA, 12% for Southeast Bering, 18% for NMFS area 509).

Bering Sea "A" Season Area and Time Comparison

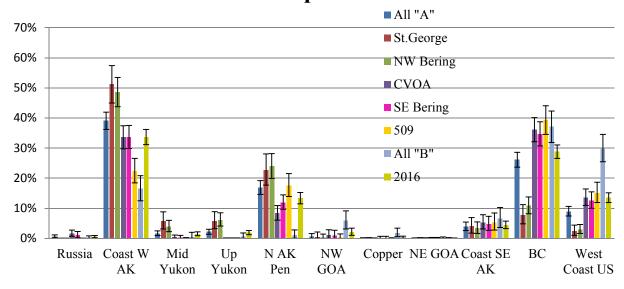

Figure 5. -- Comparison of area and time stock composition estimates from the 2016 Bering Sea Chinook salmon bycatch for "A" season: All (1,488 samples), Saint George Island (335 samples, Fig. 6), Northwest Bering (554 samples, Fig. 7), CVOA (715 samples, Fig. 8), Southeast Bering (934 samples, Fig. 7), and NMFS area 509 (501 samples, Fig. 6). Bering Sea "B" season (422 samples) and 2016 overall included for comparison. BAYES 95% credible intervals are plotted for estimates.

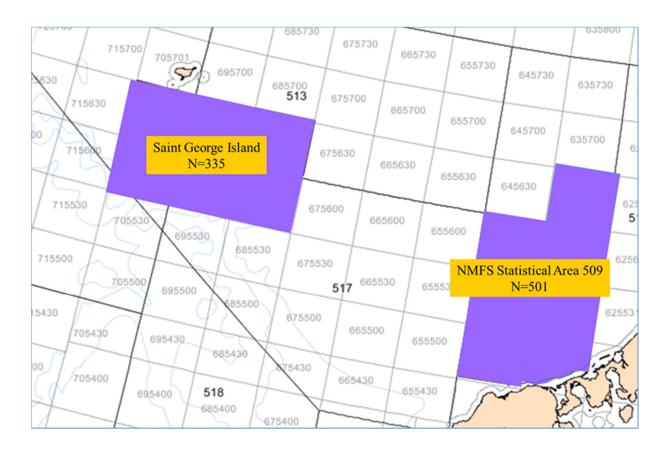

Figure 6. -- Location of Saint George Island (ADF&G Statistical Areas 705600, 695600, 685600, 705630, 695631, and 685630) and NMFS area 509 strata used in comparative stock composition estimates from the 2016 Bering Sea Chinook salmon bycatch for "A" season (NMFS 2016).

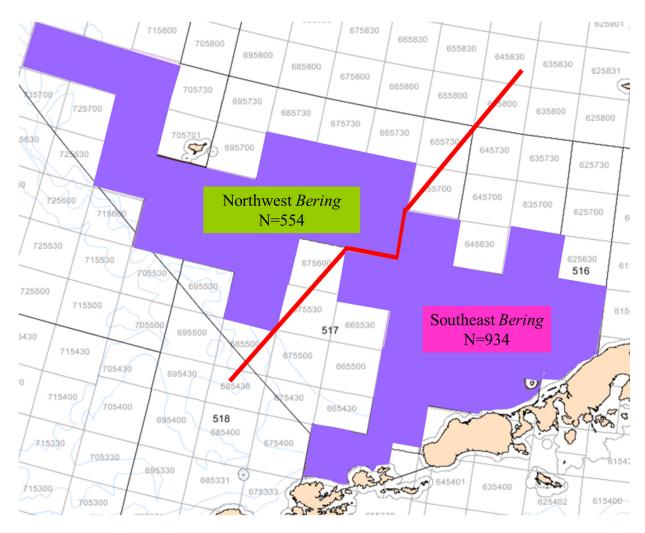

Figure 7. -- Location of Northwest Bering and Southeast Bering strata used in comparative stock composition estimates from the 2016 Bering Sea Chinook salmon bycatch for "A" season (NMFS 2016).

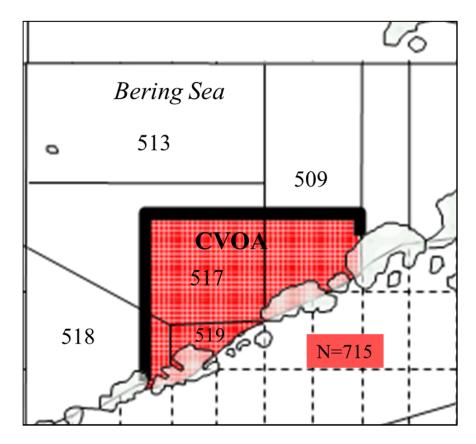

Figure 8. -- Location of Catcher Vessel Operational Area (CVOA) stratum used in comparative stock composition estimates from the 2016 Bering Sea Chinook salmon bycatch for "A" season (NMFS 2016).

For the "B" season, stock composition estimates were developed for NMFS areas 517 and 519 combined(334 samples, Figs. 1, 9, 10, Table 10) (NMFS 2016). Unlike for the 2015 samples, no estimates were developed for NMFS area 521 due to the small sample size and reduced fishing effort in this area. NMFS areas 517 and 519 had a slightly higher proportion of fish from regions southeast of the Aleutian Islands (84%), than the "B" season overall (81%).

Bering Sea "B" Season Area and Time Comparison

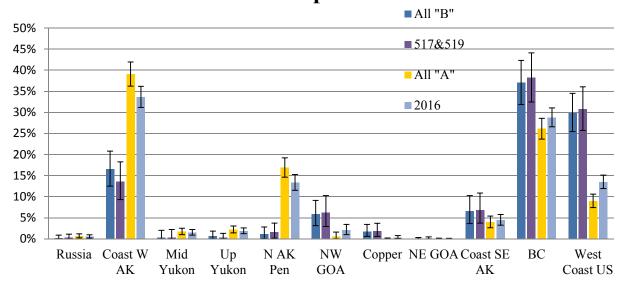

Figure 9. -- Comparison of area and time stock composition estimates from the 2016 Bering Sea Chinook salmon bycatch for "B" season: All (422 samples), and NMFS Areas 517/519 (334 samples). Bering Sea "A" season (1,488 samples) and 2016 overall included for comparison. BAYES 95% credible intervals are plotted for estimates.

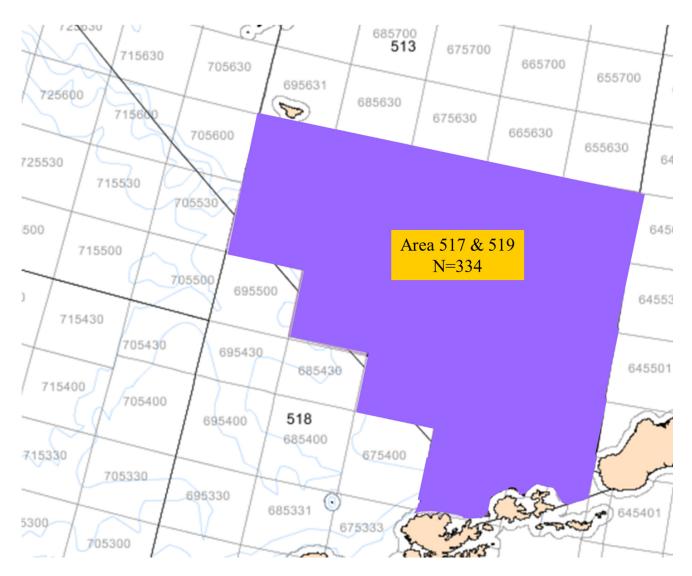

Figure 10. -- Location of samples from NMFS Statistical Areas 517 and 519 used in comparative stock composition estimates from the 2016 Bering Sea Chinook salmon bycatch for "B" season (NMFS 2016).

COMPARISON WITH PREVIOUS ESTIMATES

In contrast to 2011 and similar to most other previous years studied, most of the Chinook salmon bycatch occurred in 2016 during the "A" season. Stock compositions from the analysis of the 2016 "A" season Chinook salmon bycatch showed that most samples continued to originate from river systems directly flowing into the Bering Sea but were lower than in previous years,

with an increase from GOA, BC, and West Coast US (Fig. 11). The Coastal Western Alaska region continued to be the largest contributor in the 2016 "A" season, but was lower than in all previous years.

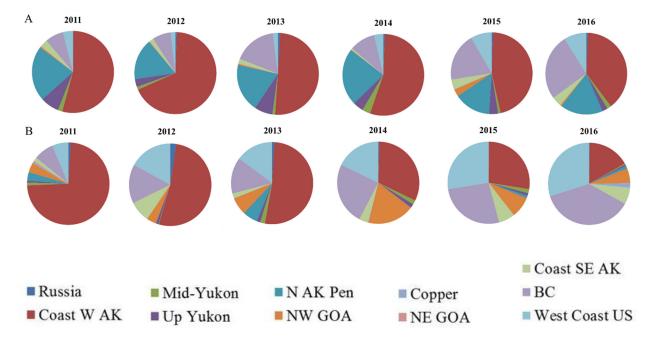

Figure 11. -- Comparison of "A" season (top) and "B" season (bottom) genetic stock composition estimates for 2011-2016 from the Bering Sea Chinook salmon bycatch. The same genetic baseline and regional groupings were used in all analyses.

The 2016 "B" season stock composition estimates from Coastal Western Alaska continued to drop as observed across 2011-2015, a 57% decline since 2011 (Fig. 11). The 2016 "B" season estimates continued the trend of increased contributions from British Columbia, West Coast US, and Coastal Southeast Alaska regions. The estimated relative contributions from these more southern regions have increased 61% since 2011 (Fig. 11).

As in previous years since 2011, systematic random sampling was employed in 2016, where genetic samples were collected from one of every 10 Chinook salmon encountered. While changes in sampling protocols prior to 2011 necessitate caution in comparing analyses across longer time periods, when the stock compositions were analyzed for the entire year, the Coastal

Western Alaska region contribution trended downward between 2008 and 2010 but increased in 2011, and then trended downward again through 2016 (Fig. 12). The North Alaska Peninsula regional contribution composed 13% of the bycatch in 2016, a slight increase from 2015 (Fig. 12). The upper and middle Yukon River, GOA, and Coastal Southeast Alaska contributions continued to be low in 2016, while contributions from the British Columbia, and West Coast US regions have trended upward (Fig. 12).

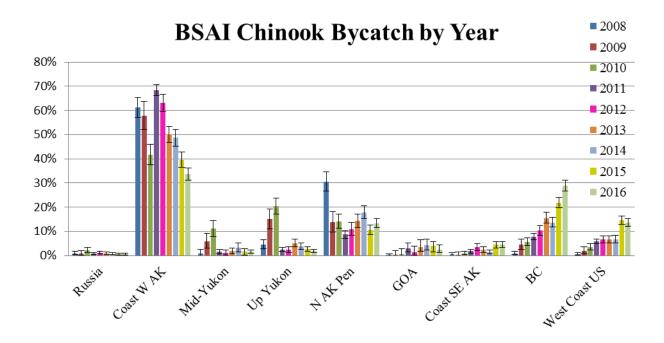

Figure 12. -- Comparison of yearly stock composition estimates (2008-2016) from the Bering Sea Chinook salmon bycatch. Estimates from 2011-2016 are overall bycatch estimates, whereas earlier estimates are of available sample sets. The same genetic baseline and general regional groupings were used in all analyses. Gulf of Alaska (GOA) group consists of combined values for Northwest GOA, Copper, and Northeast GOA. BAYES 95% credible intervals are plotted for yearly estimates.

There was interest from the NPFMC Science and Statistical Committee (SSC) April 2017 meeting on how smaller strata stock compositions might change between years so "A" season estimates were developed for the Northwest and Southeast Bering strata (Fig. 7) for which we had an adequate number of samples (Fig. 13) for analyses (NPFMC 2017c). In the Northwest

Bering stratum there is a downward trend in the Coastal Western Alaska region contribution and an upward trend in the British Columbia and North Alaska Peninsula region contributions, especially between 2015 and 2016. The trend in the Southeast Bering stratum is similar except for 2014, when the Coastal Western Alaska and North Alaska Peninsula contribution increased, with a reciprocal decline in British Columbia and West Coast US regions.

Bering Sea "A" Area and Time Comparison 120% 2013 A NW 100% ■ 2014 A NW ■ 2015 A NW 80% 2016 A NW 2013 A SE 60% ■2014 A SE ■ 2015 A SE 40% 2016 A SE 20% 0% Russia Coast W Mid Yukon Up Yukon N AK Pen GOA Coast SE BCWest Coast ΑK US ΑK

Figure 13. -- Comparison of yearly stock composition estimates (2013-2016) from the Bering Sea Chinook "A" season Northwest Bering and Southeast Bering strata. Gulf of Alaska (GOA) group consists of combined values for Northwest GOA, Copper, and Northeast GOA. BAYES 95% credible intervals are plotted for yearly estimates.

SUMMARY

Salmon-dependent communities have expressed concern regarding the numbers of salmon caught as bycatch in the Bering Sea trawl fishery (Gisclair 2009). The incidental harvest of Chinook salmon in the Bering Sea pollock fishery averaged 35,309 salmon per year between 1991 and 2016, with a peak of 121,770 in 2007 (NMFS 2017). The Bering Sea Chinook salmon bycatch has abated in more recent years dropping to a total of 21,926 Chinook salmon in 2016,

well below the 26-year average. Stock composition estimates of the Chinook salmon bycatch are needed for pollock and salmon fishery managers to understand the biological effects of the incidental take of salmon in the trawl fishery (Ianelli and Stram 2015). This report provides stock composition estimates of the Chinook salmon bycatch from the 2016 Bering Sea pollock trawl fishery. The results and limitations of this analysis are summarized below.

Sampling Issues

With the implementation of systematic random sampling in 2011, 2016 is the sixth year from which representative samples have been collected from the Chinook salmon bycatch. This represents a lot of effort over many years to develop standardized protocols for collecting sets of samples from numerous observers both at sea and in shore-based processing plants, the efforts of which are clearly apparent in the representative nature of the sample sets (Figs. 3 and 4). The number of successfully genotyped Chinook salmon from the Bering Sea bycatch samples was 1,910, corresponding to an overall sampling rate in 2016 of 8.7%.

Stock Composition Estimates

Genetic stock composition analysis showed the majority of bycatch samples collected in the Bering Sea were from Alaska originating from river systems directly flowing into the Bering Sea. The stock composition of the Chinook salmon bycatch during the 2016 "A" season differed from the 2016 "B" season, demonstrating temporal differences (Appendix 2; Fig.11). This was especially apparent in the Coastal Western Alaska (39% vs. 17%), North Alaska Peninsula (17% vs. 1%), NW GOA (1% vs. 6%), British Columbia (26% vs. 37%), and West Coast US (9% vs. 30%) stock groups. Spatial analysis showed that the stock compositions varied within season depending upon where the salmon in the bycatch were caught. For example, during the "A"

season there was a higher concentration of Western Alaska origin Chinook intercepted in the northern areas of the Bering Sea, and southern (south of the Aleutians) origin Chinook intercepted in the southern areas of the Bering Sea (Fig. 5). One must also consider that the bycatch in the "A" season is over three times greater than the "B" season, and that the stock composition differences may be due to seasonal migration of stocks. For example, the estimated number of West Coast US fish only slightly increases from 1,506 in the "A" season to 1,524 in the "B" season (Appendix 2), while its proportion increases from 9% to 30%, likely due to the absence or lower proportion of other stock groups.

Application of Estimates

The extent to which any salmon stock is impacted by the bycatch of the Bering Sea trawl fishery is dependent on many factors including 1) the overall size of the bycatch, 2) the age of the salmon caught in the bycatch, 3) the age of the returning salmon, and 4) the total annual escapement of the affected stocks. As such, a higher contribution of a particular stock one year does not necessarily imply greater impact than a smaller estimate the next. Stock composition estimates for the 2016 Bering Sea Chinook salmon bycatch were considered to be representative of the overall bycatch for this year.

ACKNOWLEDGMENTS

We are grateful for the help from the AFSC's FMA Program, the many participating observers who provided genetic samples. Thanks to Rob Ames and Bob Ryznar for developing AKFIN Answer reports that helped us develop new strata for genetic analyses. We are grateful to Chris Habicht, Andrew Munro and Dani Evenson of ADF&G, and AFSC's Drs. Christine Kondzela and Jordan Watson for their thoughtful reviews of this report. Special thanks to AFSC Communications Program staff, especially James Lee, for their rapid and thorough editorial review of this document.

Appendix 2. -- Regional BA YES stock composition percentage estimates and estimated numbers of different strata of Chinook salmon from the 2016 Bering Sea pollock trawl fisheries. The BA YES mean estimates are also provided with standard deviations (SD), 95% credible intervals, and the median estimate. Sample sizes are adjacent to stratum designation. Total catch is the actual catch for each stratum from AKFIN reports (NMFS 2017). Figures 1, 3, 6, 7, 8 and 10 show strata locations and timing
