Appendix D: Methods used by participating laboratories.

Abstract

In support of environmental monitoring measurement programs, the National Institute of Standards and Technology (NIST) conducts inter-laboratory comparison exercises to provide one mechanism for participating laboratories/monitoring programs to evaluate the quality and comparability of their performance in measuring selected organic contaminants in environmental samples. Polybrominated diphenyl ethers (PBDEs) are brominated flame retardants that are now becoming a contaminant of emerging concern. Many studies have reported different analytical methods for measuring these contaminants in environmental samples; however, very few inter-comparison exercises have been conducted on the measurements of PBDEs in environmental samples. The one major comparison that was conducted has shown large variations in measurement values¹. This report describes the results from the NIST 2004 exercise for the determination of PBDE congeners in marine sediments. Summaries are provided with the results received from twelve participating laboratories from six different countries. A detailed analysis of the measurement variability for eight individual BDE congeners is provided. The analytical methods used by each participating laboratory are also included.

Introduction

Polybrominated diphenyl ethers (PBDEs) are flame retardant chemicals added to numerous textiles, rubbers and polymeric materials. PBDEs are now considered to be ubiquitous contaminants, and much attention has been focused on their fate and transport in the environment. Due to increased attention, many laboratories have been studying different methods to measure the suite of 209 possible isomers of PBDEs. These compounds (see Figure 1) are similar in structure to polychlorinated biphenyls (PCBs) and are labeled according to the same IUPAC labeling scheme.

Polybrominated Diphenyl Ether (PBDE)

Figure 1. Structure of polybrominated diphenyl ethers. PBDEs can have from one to ten bromine atoms substituted around the diphenyl ether backbone.

Due to increased attention and potential policy implications, the ability of laboratories to accurately determine and measure PBDEs has become important. Tools and mechanisms for the assessment of data produced by laboratories providing environmental analyses are critical because decision-making based on inaccurate results or data of unknown quality can have significant economic and health consequences. The National Institute of Standards and Technology (NIST) offers a variety of activities in support of environmental monitoring programs with the goal of improving measurements for monitoring organic contaminants. The current inter-comparison exercise was undertaken to assess the variability in PBDE measurements made by different laboratories which analyze the same reference materials using different extraction and/or detection methods. This exercise followed up on an earlier inter-comparison exercise which found large variations in the accuracy of PBDE measurements ¹.

Current participants in this study represent multi-laboratory monitoring programs as well as a number of individual programs, and include federal, state/municipal, university/college, private sector, and international laboratories. In this performance based program, each participating laboratory uses its current methods for analysis of similar materials that it would use for its program customers. The target PBDE congeners are listed in Table 1.

Sources and Preparation of Materials used in 2004 Inter-comparison Exercise

Two marine sediment Standard Reference Materials (SRMs) were distributed to each participating laboratory. These two SRMs, SRM 1941b (Organics in Marine Sediment) and SRM 1944 (New York/New Jersey Waterway Sediment) have been certified for other organic contaminants such as polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs) and organochlorine pesticides. SRM 1941b contains sediment collected from the Chesapeake Bay near the mouth of the Baltimore Harbor adjacent to the Francis Scott Key Bridge and is certified for 24 PAHs, 29 PCBs and 7 organochlorine pesticides. SRM 1944 was collected from six different sites along New York Bay and Newark Bay in 1994 and is certified for 24 PAHs, 35 PCBs, and 4 organochlorine pesticides. The sediment in both SRMs has been freeze-dried, sieved to 150 μ m (SRM 1941b) or <60 μ m (SRM 1944), homogenized in a cone blender, and radiation sterilized (⁶⁰Co) prior to bottling and analysis.

Storage and Distribution of Materials

Each bottle of marine sediment SRM was stored at room temperature in amber jars until shipped to each participating laboratory. Each participating laboratory in this intercomparison exercise was sent one bottle each of SRMs 1941b and 1944. In the letter accompanying the shipments, participants were asked to analyze three replicate samples of each SRM in order to provide a more realistic assessment of laboratory precision. In addition each laboratory was requested to provide a brief description of their extraction, cleanup, and analytical procedures. SRMs were sent to the laboratories in August 2004. Laboratories were requested to submit results for the exercise by December 31, 2004. However, an extension was offered to several laboratories, and all data were submitted by March 30, 2005.

Evaluation of Exercise Results

Establishment of the Assigned Values

The following guidelines were used by the NIST exercise coordinators for the establishment of the exercise "Assigned Values". Each laboratory was asked to submit data from three replicate determinations of PBDEs in the SRMs. For each laboratory, the laboratory analyte mean of the three sample results (S1, S2, and S3) was calculated for each analyte. Non-numerical data were treated as follows: A mean "<value" was used when three "<values" were reported; NA (not analyzed/determined) was used for three

reported NAs; and, if the reported results were of mixed type, e.g., S1 and S2 were numerical values and S3 was reported as "<value", the two similar "types" were used to either determine the mean or to set a non-numerical descriptor.

For this exercise, the assigned value for each analyte was the geometric mean value of all reported values for each analyte, with the exception of BDE 209 in which the median value was used. Several laboratories reported BDE 209 values that were significantly outside the range of values reported by a majority of the participating laboratories when examined on both normal and log normal distribution plots of the data (see Appendices A and B). See Tables 2 and 3 for a listing of the reported values.

In instances in which the analyte concentration was below the detection limit of most participating laboratories, no exercise assigned value was calculated. In this data set, enough data were only available to establish assigned values for eight individual BDE congeners. In data sets such as this with a number of laboratories reporting results as "not detected" at various detection limits, there is no consensus as to what numerical value should be assigned to these results in the computation of grand means, etc.; e.g., "0", half Detection Limit (DL), and the DL value itself have all been used and the choice is influenced by the intended use of the particular data set.

Reported Results

Laboratories were assigned random numerical identification codes. There are two sets of results generated by NIST from the Gaithersburg, MD laboratory and the Charleston, SC laboratory. A laboratory was assigned the same code for each SRM analysis. The mean value reported by each laboratory is presented in Tables 2 and 3 in addition to the exercise assigned value and standard deviation of the assigned values for the eight BDE congeners. In this report, the triplicate results as reported by the laboratory's z-scores (see next section labeled "Performance Scores" for an explanation of z-scores) for the eight BDE congeners that had assigned values.

Performance Scores

The exercise coordinators recognize that different programs have different quality needs. The acceptability of the results submitted by a particular laboratory will be decided by the individual program(s) for which the particular laboratory provides data. Typically, the program will use these exercise results in conjunction with the laboratory's performance in the analysis of certified reference materials and/or control materials, and other quality assurance samples. These exercise results are exhibited in a number of ways in this report to facilitate their use by these programs in their acceptability assessments.

IUPAC guidelines² describe the use of z-scores for assessment of accuracy in intercomparison exercises such as those described in this report. This index assesses the

difference between the results of the laboratory and the exercise assigned value and can be used, with caution, to compare performance on different analytes and on different materials.

Accuracy Assessment (z-scores)

z-score = (bias estimate)/(performance criterion) = $(x-X)/\sigma$

where x is the average of the individual laboratory results, X is the "Exercise Assigned Value" (exercise mean in this report), and σ is the target value for standard deviation.

As described in the IUPAC guidelines, the choice of σ is dependent upon data quality objectives of a particular program. It can be "fixed" and arrived at by perception, prescription, or reference to validated methodology (e.g., $\sigma = 0.20$ X, where X is the analyte concentration), or it can be an estimate of the actual variation (e.g., the calculated sample standard deviation, *s*, from the exercise data). The "fixed" performance criterion is more useful in the comparison of a laboratory's performance on different materials while the use of the actual variation may be more useful within a given exercise, for example, if the determination of a particular analyte is exceptionally problematic.

We have calculated and reported z-scores using a fixed performance criterion, where $\sigma = 0.20$ X. The z-scores calculated for these exercises can thus be interpreted as shown in the following examples:

z-score (20% X): +1 \rightarrow laboratory result is 20% higher than the assigned value -2 \rightarrow laboratory result is 40% lower than the assigned value

From a scientific point of view, IUPAC does not recommend the classification of zscores but allows for a common classification as:

| z | $ \leq 2$ z < 3 | Satisfactory |
|-----|----------------------|----------------|
| 2 < | z < 3 | Questionable |
| z | l ≥ 3 | Unsatisfactory |

Tables 4 and 5 report the z-scores for each laboratory's measurement of the eight BDE congeners for which values were assigned. These tables include a summary of the number of reported analytes that fall within each category for each laboratory.

Discussion

Laboratories were asked to quantify 34 individual PBDE congeners (see Table 1). Thirteen laboratories expressed interest in participating in this exercise, and twelve laboratories from six different countries returned results for both SRMs (see Appendix C). A majority of the laboratories supplied results for the eight most common PBDE congeners measured in environmental samples (BDE 28, BDE 47, BDE 99, BDE 100, BDE 153, BDE 154, BDE 183 and BDE 209). Exercise values were therefore established for these eight congeners, and z-scores were calculated for each laboratory as a measure of exercise comparability.

In general, data obtained for individual PBDE congeners were normally distributed (tested by the Shapiro Wilks test; see Appendix B). Exercise values were established for the data by taking the geometric mean of the data. However, results for BDE 209 (in both SRMs) were not normally distributed (p<0.01; Shapiro Wilks test). Since the BDE 209 data were not normally distributed and because there were a few large outliers in the data, the BDE 209 median value (taken from reported laboratory data) was used as the exercise value for BDE 209 (see Tables 2 and 3). Two laboratories that used sonication as an extraction method were observed to report BDE 209 levels that were significantly below the exercise value for BDE 209 (see Appendix D). Two laboratories reported BDE 209 levels that were significantly above the exercise value for BDE 209 and some investigations into the extraction and quantification of BDE 209 may be warranted. (Since the first release of this document in April 2005, Laboratory 12 has discovered that the concentration of BDE 209 in their BDE 209 calibration solution was incorrect, resulting in their high reported values for BDE 209.)

The assigned values for the eight PBDE congeners ranged from 0.08 ng/g \pm 0.09 ng/g dry mass (BDE 183 in SRM 1941b) to 127 ng/g \pm 411 ng/g dry mass (BDE 209 in SRM 1944). BDE 209 was the dominant congener measured in both sediment SRMs which is similar to patterns observed in environmental sediment samples³. In general, PBDE concentrations were higher in SRM 1944 relative to SRM 1941b. The z-scores for the BDE congeners based on 20% of the exercise assigned value are included in Tables 4 and 5. A majority of the z-scores, based on 20%, for each laboratory are within \pm 2. Of the reported values for SRM 1941b, only 12% of the z-scores were >3. Of the reported values for SRM 1944, only 9% of the z-scores were >3. Z-scores calculated for BDE 209 among the laboratories displayed the widest variation (0.00 to 52.5).

Sulfur complexes are commonly found in sediment matrices and are very abundant in these two SRMs. Multiple techniques are used to remove sulfur from the extracts (e.g. activated copper), however, residual sulfur may still be present and cause matrix interferences upon gas chromatography with mass spectrometric (GC/MS) or with electron capture (GC/ECD) analysis. A recent paper has shown that zero valent iron and iron sulfides can reductively debrominate PBDEs, particularly BDE 209⁴. Therefore, the large relative standard deviations observed for the measurement of BDE 209 in these SRMs may be due to sulfur interferences. More work is needed to determine the role that sulfur complexes play in the extraction and measurement of PBDEs in these SRMs.

Inter-comparison exercises provide an important mechanism for assessing the comparability, accuracy, precision, and reproducibility of data being produced by the participating laboratories. Exercise materials similar in matrix, form, and analyte concentration to samples routinely analyzed by the laboratories are most useful for demonstrating the level of comparability and for revealing potential problem areas. For the determination of relatively low levels of PBDEs in these complex matrices, the levels of bias and reproducibility of many of the participating laboratories meet their current acceptability requirements; however, there is certainly room for improvement. Minimizing the among-laboratory biases so that the analytical variability is significantly less than the sampling variability should be an achievable goal.

Acknowledgments

The time and efforts of the analysts and management of the participating laboratories and the assistance of the NIST Standard Reference Materials Program for the procurement and preparation of the exercise materials are gratefully acknowledged.

Table 5. Data as Submitted By Laboratory for SRM 1944 (concentration in ng/g dry mass)

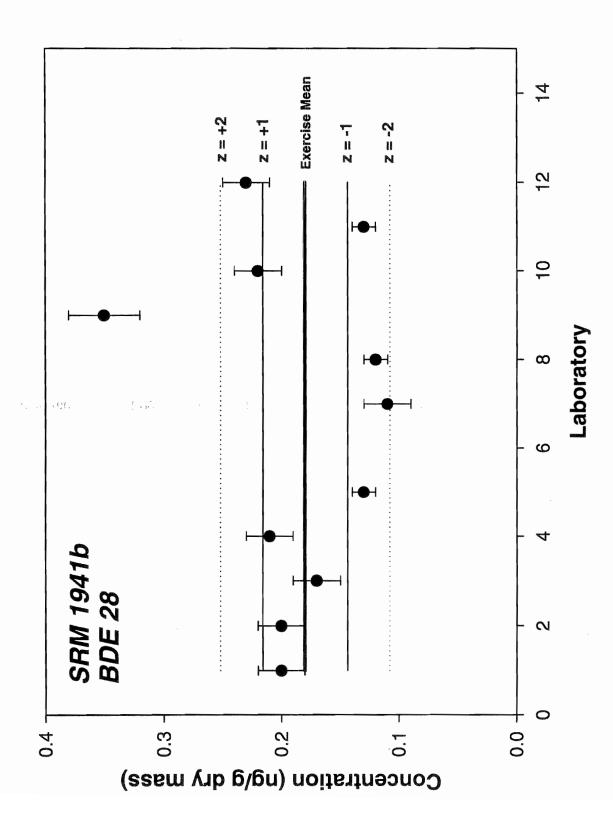

Appendix A: Charts of SRM 1941b and SRM 1944 by BDE congener

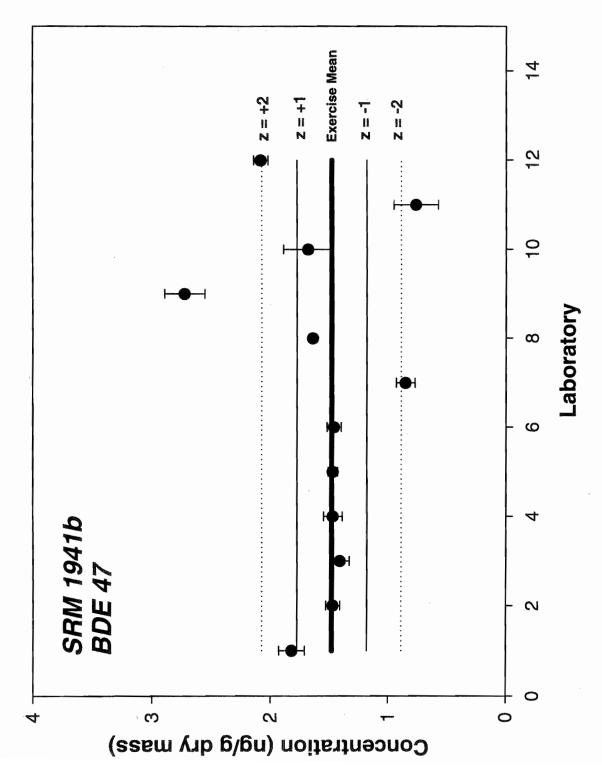

Solid line: exercise assigned value (geometric mean)

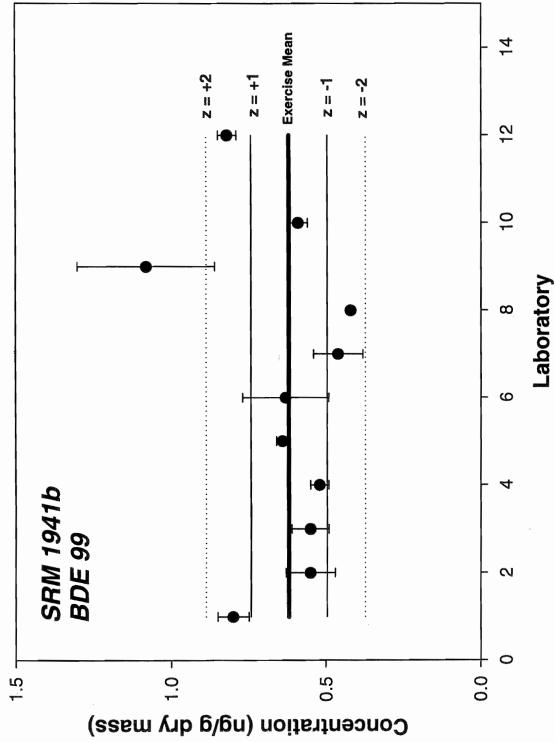

Thin line: $z = \pm 1$, i.e., 20% from assigned value

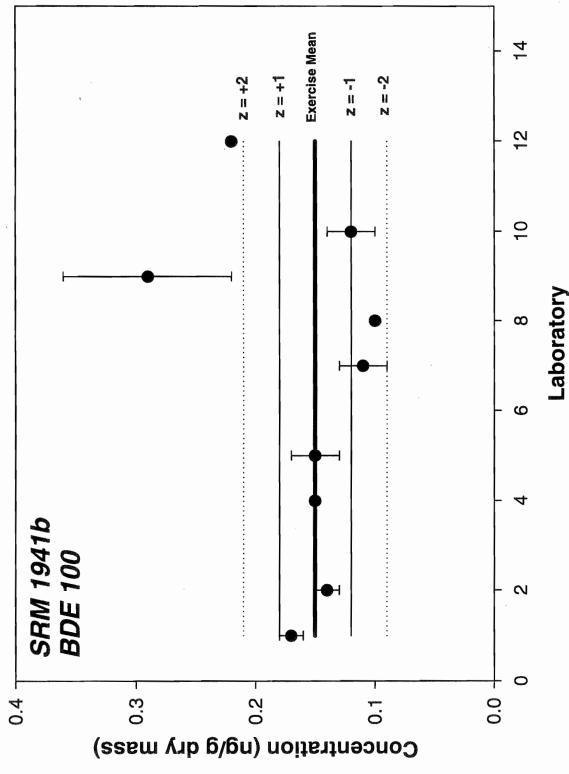

Dashed line $z = \pm 2$ i.e., 40% from assigned value

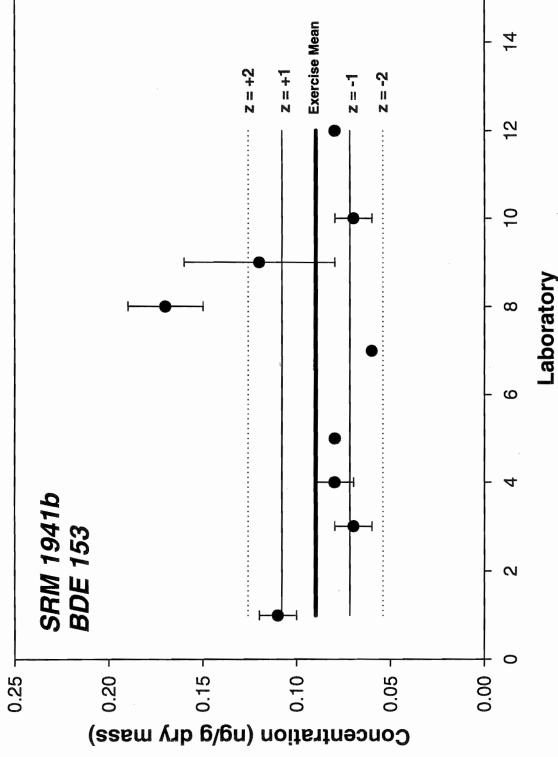

Error bars represent one standard deviation

Appendix C: List of Laboratories Participating in 2004 Inter-Comparison Exercise on PBDEs in Sediment SRMs

For this exercise, data were received from the following laboratories within the required timeframe. (This listing does NOT correspond to the laboratory number identification codes used in this report.)

Axys Analytical Services Ltd. 2045 Mills Rd. Sidney, British Columbia, Canada V8L 3S8 Dale Hoover/ Coreen Hamilton

Chesapeake Biological Laboratory 1 Williams Street P.O. Box 38 Solomons, MD 20688 U.S.A. Susan Klosterhaus/Joel Baker

Environment Canada Ecosystem Health Division Environmental Conservation Branch, Ontario Region 867 Lakeshore Road, P.O. Box 5050 Burlington, Ontario, Canada L7R 4A6 Sean Backus

Environment Canada Canada Centre for Inland Waters 867 Lakeshore Rd. Burlington, Ontario Canada L7R 4A6 Ed Sverko

Federal Environmental Agency Laboratory for Water Analysis, II 2.5 Bismarckplatz 1, 14193 Berlin, Germany Peter Lepom

Indiana University 1005 E. 10th St. Geology 541 Bloomington IN 47405, USA Ron Hites/Lingyan Zhu

NIST – Charleston Laboratory 219 Fort Johnson Road Charleston, SC 29412-9110 USA Jennifer Keller NIST-Gaithersburg 100 Bureau Drive Mailstop 8392 Gaithersburg, MD 20899 USA Heather Stapleton

Research Center for Eco-Environmental Sciences Chinese Academy of Sciences 18 Shuangqing Road, Haidian District, Beijing, China Post Code: 100085 Guibin Jiang

Tokyo University of Agriculture & Technology Fuchu, Tokyo 183-8509, Japan Hideshige Takada

University of Antwerp (U.A.) Toxicological Centre Universiteitsplein 1 2610 Wilrijk (Antwerpen), Belgium Adrian Covaci/Stefan Voorspoels

University of Illinois at Chicago Environmental and Occupational Health Sciences School of Public Health 2121 W. Taylor Street, MC 922 Chicago, IL 60612 USA An Li
